COMP2521

Generic ADTs in C
Function Pointers

• C can pass functions by passing a pointer to them.
• Function pointers ...
  – are references to memory addresses of functions
  – are pointer values and can be assigned/passed

• Function pointer variables/parameters are declared as:
  
  `typeOfReturnValue (*fp)(typeOfArguments)`

• In the following example, `fp` points to a function that returns `int` and have one argument of type `int`.
  
  `int (*fp)(int)`
Function Pointers

int square(int x) { return x*x;}

int timesTwo(int x) { return x*2;}

int (*fp)(int);

fp = &square; //fp points to the square function

int n = (*fp)(10); //call the square function with input 10

fp = timesTwo; //works without the &
   //fp points to the timesTwo function

n = (*fp)(2); //call the timesTwo function with input 2

n = fp(2); //can also use normal function call
   //notation
Higher-order Functions

• Functions that get other functions as arguments, or return functions as a result

• **Example:** the function `traverse` takes a list and a function pointer (`fp`) as argument and applies the function to all nodes in the list

```c
void traverse (list ls, void (*fp) (list)){
    list curr = ls;
    while(curr != NULL){
        // call function for the node
        fp(curr);
        curr = curr->next;
    }
}
```

Second argument is `fp`, Pointer to a function like, `void functionName(list n)`
Higher-order Functions: Example

```c
void printNode(list n) {
    if(n != NULL) {
        printf("%d->", n->data);
    }
}
```

```c
void printGrade(list n) {
    if(n != NULL) {
        if(n->data >= 50) {
            printf("Pass");
        } else {
            printf("Fail");
        }
    }
}
```

```c
void traverse (list ls, void (*fp) (list));

//The second argument must have matching prototype

traverse(myList, printNode);
traverse(myList, printGrade);
```
Generic Types in C

• **Polymorphism**: refers to the ability of the same code to perform the same action on different types of data.

• There are two primary types of polymorphism:
  
  – Parametric polymorphism: The code takes the type as a parameter, either explicitly (as C++ and Java) or implicitly (say as in C)

  – Subtype polymorphism: Subtype polymorphism is associated with inheritance hierarchies.

Generic Types in C

- **Polymorphism in C:**
  C provides pointer to void (for example, `void *p`), the programmer can create generic data types by declaring values to be of type "void *". For example:

  ```c
  struct Node {
    void *value;
    struct Node *next;
  };
  ```

  The programmer can pass in type-specific functions (e.g., comparator functions) that take void *'s as parameters and that downcast the void *'s to the appropriate type before manipulating the data.

  For example, the example on the next page has a generic min function that computes and returns the minimum of two elements. The sample program compares two strings.
#include <stdio.h>
#include <string.h>

// generic min function
void *min(void *element1, void *element2, int (*compare)(void *, void *)) {
    if (compare(element1, element2) < 0)
        return element1;
    else
        return element2;
}

// stringCompare downcasts its void * arguments to char * and then passes
// them to strcmp for comparison
int stringCompare(void *item1, void *item2) {
    return strcmp((char *)item1, (char *)item2);
}

int main(int argc, char *argv[]) {
    if (argc != 3) {
        printf("usage: min string1 string2\n");
        return 1;
    }

    // call min to compare the two string arguments and downcast the return
    // value to a char *
    char *minString = (char *)min(argv[1], argv[2], stringCompare);

    printf("min = %s\n", minString);
    return 0;
}
Generic Types in C

Advantages
• One copy of the code works with multiple objects.
• The approach supports both generic data structures and generic algorithms.

Disadvantages
• Downcasting can be dangerous, since run-time type checks are not performed in C.
• The code often has a cluttered appearance.
