What did we learn yesterday?

Linked Lists

- Some Revision
- Building Lists
- Insertion into Lists
What are we doing today?

More Linked Lists

- Finding something in a list
- Insertion to keep a list alphabetical
- Linked List Removal
- Freeing our Allocated Memory
- Playing the game
Insertion with some conditions

We can now insert into any position in a Linked List

- We can read the data in a node and decide whether we want to insert before or after it
- Let's insert our elements into our list based on alphabetical order
- We're going to use a `string.h` function, `strcmp()` for this
- `strcmp()` compares two strings, and returns
  - 0 if they're equal
  - negative if the first has a lower ascii value than the second
  - positive if the first has a higher ascii value than the second
Finding where to insert

We're going to loop through the list

● This loop assumes the list is already in alphabetical order
● Each time we loop, we're going to keep track of the previous player
● We'll test the name of each player using `strcmp()`
● We stop looping once we find the first name that's "higher" than ours
● Then we insert before that player
Finding the insertion point

Attempting to insert a player with name: "D" into a sorted list while maintaining the alphabetical order

Insert between these two players
Inserting into a list Alphabetically

```
struct player *insertAlphabetical(char newName[], struct player* head) {
    struct player *previous = NULL;
    struct player *p = head;
    // Loop through the list and find the right place for the new name
    while (p != NULL && strcmp(newName, p->name) > 0) {
        previous = p;
        p = p->next;
    }
    struct player *insertionPoint = insert(newName, previous);
    // Return the head of the list (even if it has changed)
    if (previous == NULL) { // we inserted at the start of the list
        insertionPoint->next = p;
        return insertionPoint;
    } else {
        return head;
    }
}
```
Removing a player

If we want to remove a specific player

- We need to look through the list and see if a player name matches the one we want to remove
- To remove, we'll use **next** pointers to connect the list around the player node
- Then, we'll free the node itself that we don't need anymore
Removing a player node

If we want to remove the Second Player

A program's memory (not to scale)
Skipping the player node

Alter the First Player's **next** to bypass the player node we're removing.

A program's memory (not to scale)

- **First Player**
  - *Next* to Marc
  - *Next* to Tom

- **Second Player**
  - *Next* to Tom

- **Third Player**
  - *Next* to Goku

First Player bypasses Second Player
Freeing the removed node

Free the memory from the now bypassed player node

A program's memory (not to scale)

First Player

Next

Marc

Head

Second Player

Next

Tom

Free this node

Third Player

Next

Goku

NULL
Break Time

Keeping track of your own code projects

- Using **git** is a really handy way to keep backups of your work
- GitHub and BitBucket are two providers that will give you free online repositories to store your code
- Graphical Interfaces are available for git (GitHub Desktop and Sourcetree respectively)
- It takes some time to get familiar with how these work . . . but you can start practicing now!
Finding the right player

Loop until you find the right match

This is very similar to finding the insertion point earlier

```c
struct player *removePlayer(char name[], struct player* head) {
    struct player *previous = NULL;
    struct player *current = head;
    // Keep looping until we find the matching name
    while (current != NULL && strcmp(name, current->name) != 0) {
        previous = current;
        current = current->next;
    }
    if (current != NULL) {
        // if current isn't NULL, we found the right player
    }
}
```
Removing a player

Having found the player node, remove it from the list

```c
if (current != NULL) {
    // if current isn't NULL, we found the right player
    if (previous == NULL) {
        // it's the first player
        head = current->next;
        head = current->next;
    } else {
        previous->next = current->next;
    }
    free(current);
}
return head;
```
The Battle Royale

In a Battle Royale, people are removed from the game one at a time until only one person is left. They are the winner.

- We can create a list of players
- We can make sure it's in a nice alphabetical order
- We can remove a single player from the list
- Now we need to remove players one at a time
- When there's only one left, they are the winner!
Game code

Once our list is created, we can loop through the game

- We print out the player list (we might want to modify that function!)
- Our user will tell us who was knocked out

```c
// A game loop that runs until only one player is left
while (printPlayers(head) > 1) {
    printf("Who just got knocked out?\n");
    char koName[MAX_NAME_LENGTH];
    fgets(koName, MAX_NAME_LENGTH, stdin);
    koName[strlen(koName) - 1] = '\0';
    head = removePlayer(koName, head);
    printf("----------\n");
}
printf("The winner is: %s\n", head->name);
```
Cleaning Up

Remember, All memory allocated (malloc) needs to be freed

- We can run `dcc --leak-check` to see whether there's leaking memory
- What do we find?
- There are pieces of memory we've allocated that we're not freeing!

Let's write a function that frees a whole linked list

- Loop through the list, freeing the nodes
- Just be careful not to free one that we still need the pointer from!
Looping to free nodes

A program's memory (not to scale)

First Node
  Next: 3

Second Node
  Next: 2

Third Node
  Next: 1

Loop pointer

head

NULL
Looping to free nodes

A program's memory (not to scale)

First Node
Next 3

Pointer to node we're freeing

Save a pointer to the node we're freeing

Second Node
Next 2

Loop pointer

Third Node
Next 1

Loop pointer is copied from First Node's next before we free First Node

NULL
Looping to free nodes

A program's memory (not to scale)

We can free the node now that we've copied its Next

Pointer to node we're freeing

Loop pointer
void freeList(struct node *n) {
    while (n != NULL) {
        struct node *remNode = head;

        n = n->next;

        free(remNode);
    }
}
Battle Royale, the Linked Lists demo

What have we written in this program?

- Creation of nodes
- Looping through a list
- Insertion of nodes into specific locations
- Finding locations using loops
- Removal of nodes
- Managing memory
What did we cover today?

Linked Lists

- Finding a particular node for insertion
- Removal
- Removing a specific node
- Memory cleaning
