

# **ENGG1811 Computing for Engineers**

## **Week 1**

### **Introduction to Programming and Python**

# Computers have changed engineering ...

<https://blog.sipa>

techniques

# Computers have changed engineering ...

# How computing is used in engineering?

- *Automation* is a major application of computing in engineering
  - There are many other applications of computing in engineering. More to come.
  - Message: *Computing will play a key role in addressing grand challenges in engineering, e.g., aging infrastructure, etc.*
  - <http://www.engineeringchallenges.org>
- Automation: Computers/machines repeatedly performing the same procedure
  - Procedure: a sequence of *instructions*

# Problem solving

- Engineering: **invention, problem solving, ...**
- Problem solving requires you to understand how things work, test out ideas etc.
- **How can you use computers to solve problems for you?**
  - How can you use computers to understand, investigate, test and design?

# Programming

- If you come out with a method for the computer to solve a problem, you need to be able to tell the computer how to do it.
  - You need to give instructions to computers
- Programming skill: The ability to give instructions to computers to perform the intended tasks

# A role-play game

- We will play a game on giving instructions to “computers”
- We need a volunteer or two volunteers working together
- The lecturer will provide the instructions of this game

# Python

- Python will be the programming language that you will use to learn how to give instructions to computers
- It is a popular programming language and it comes with a lot of extra packages that help you to do engineering work
- We use **Python 3**, not Python 2.

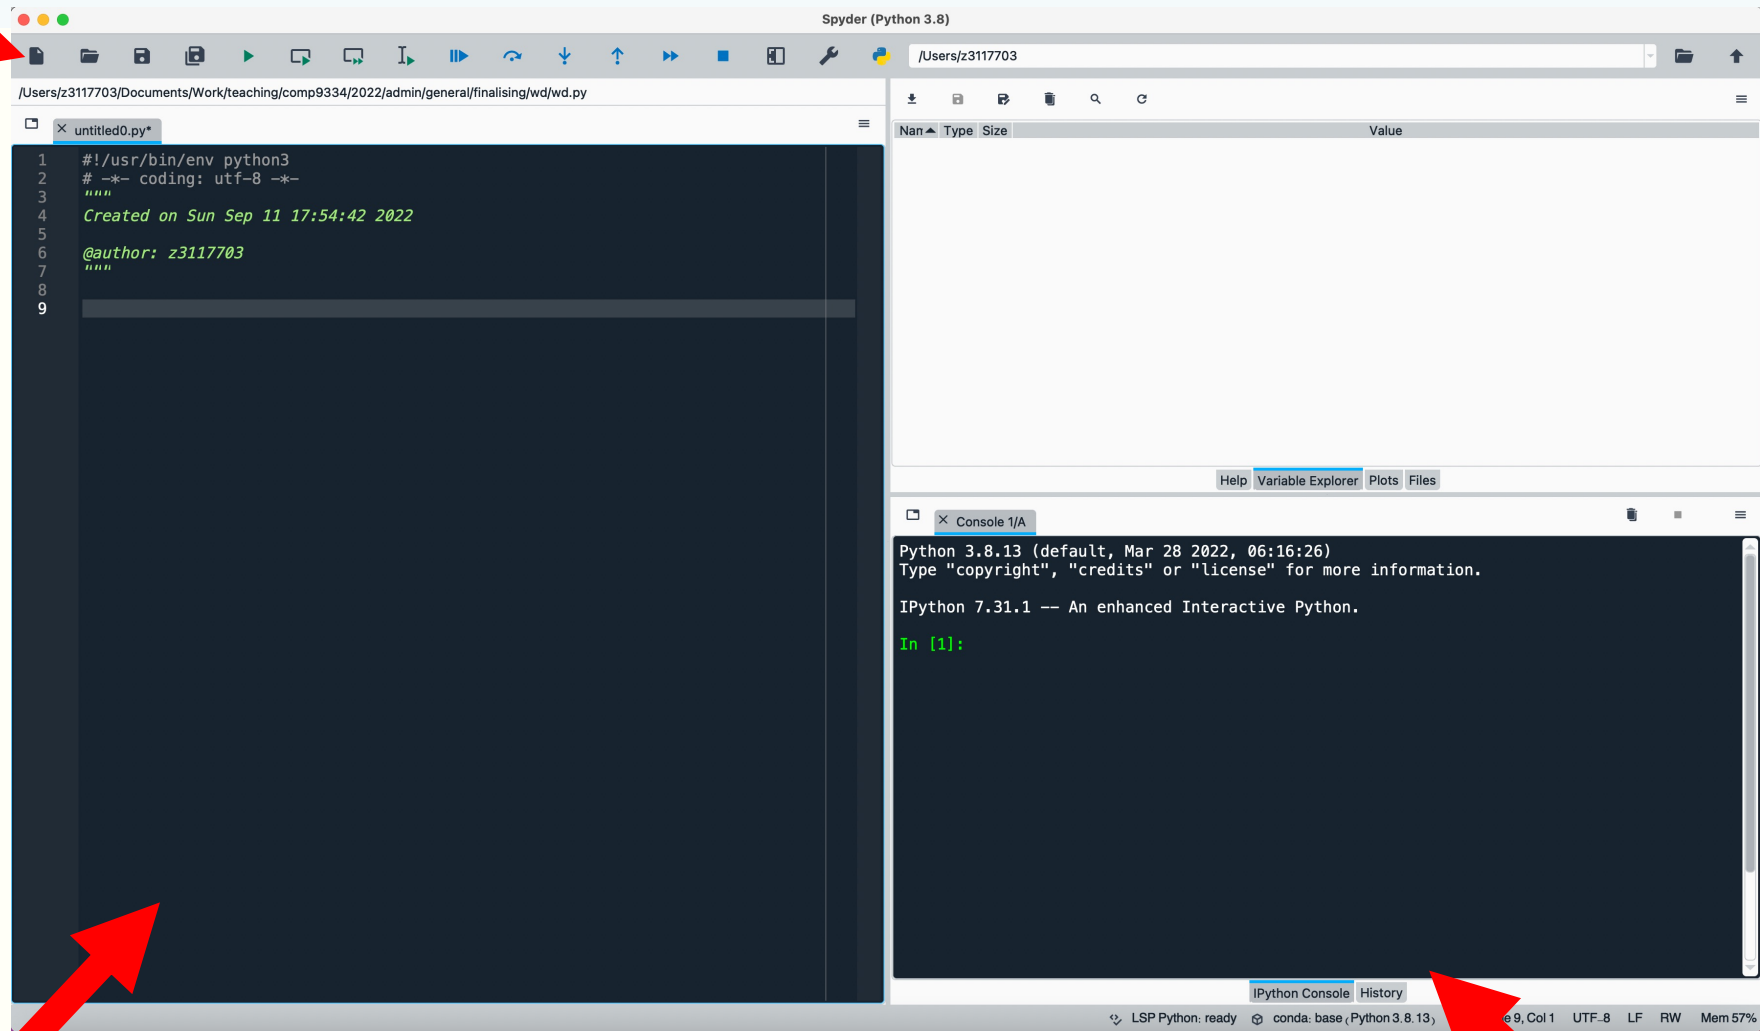

# Spyder

- We will use a program called Spyder to develop, test and run Python programs
- Spyder is available on all UNSW CSE computers
- You will also use Spyder in the lab
- If you want to use Spyder on your computer, your options are:
  - Install Anaconda on your computer
  - Use the UNSW CSE computers remotely. This requires Internet access.
  - More details in the Getting Started section of the course website

# The Spyder Environment

## Buttons

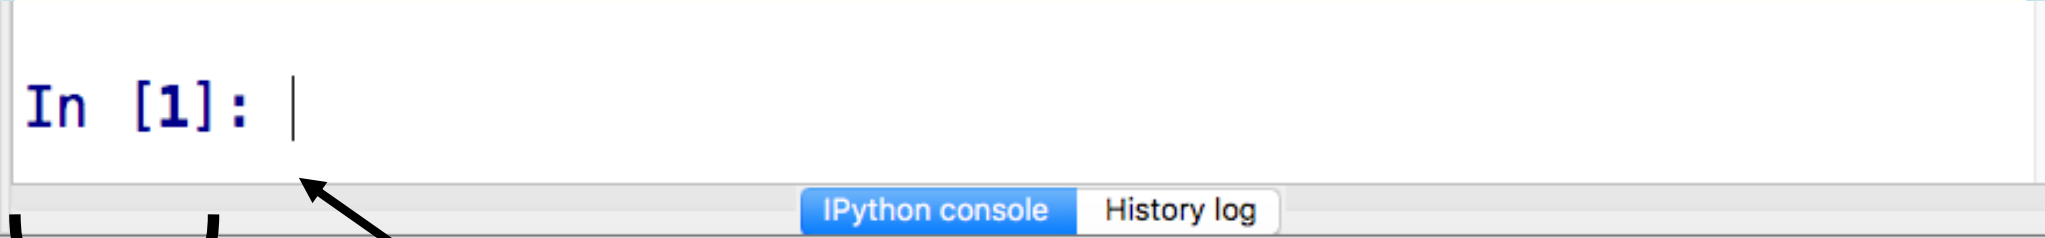

**Editor for developing  
Python programs**

**iPython Console  
'i' is short for interactive**

# Using the iPython Console

- We will simply call it the console
- You can use the console to do some simple programming
- You do that by typing commands at the prompt
  - Commands are instructions to tell the computers to do something

In [1]: |

The screenshot shows the iPython console interface. At the top left, the text 'In [1]:' is displayed in blue, followed by a vertical line representing a blinking cursor. Below this, there is a horizontal bar with two tabs: 'iPython console' (highlighted in blue) and 'History log'. A black bracket is drawn under the 'In [1]:' text, and a black arrow points from the explanatory text below to the cursor.

The  
prompt

You type the command at the blinking cursor. After you've finished typing, use the Enter (or Return) key to tell the console to execute the commands.

# If you haven't got Spyder yet,

- You can use iPython Console online at:
  - <https://www.pythonanywhere.com/try-ipython/>
  - <https://trinket.io/console>
- We will only be using iPython Console today but we will use the editor in the next lecture. So make sure you install Anaconda before that.
  - Instructions on installing Anaconda for Python 3 can be found under Getting Started on the course website
  - Notes for 24T3:
    - Mac users are asked to install an earlier release of Anaconda
    - Windows users should install the latest release

# Using console to do arithmetic

- Type 3+4 at the console, as follows:

```
In [1]: 3 + 4
```

IPython console

History log

- And then type the Enter key
- The computer execute the instruction, which is to add 3 and 4
- The console returns the answer

```
In [1]: 3 + 4
```

```
Out[1]: 7
```

```
In [2]:
```

IPython console

History log

# Arithmetic Operators in Python

Operator	Description
+	Addition or unary plus
-	Subtraction or unary minus
*	Multiplication
/	Floating point division
//	Integer division (fraction discarded)
%	Integer modulus (remainder)
**	Exponentiation (power)

# Exercises:

- Type the following at the prompt and then execute the command, observe what you get and try to understand the meaning of the arithmetic operators

`2 * 4`

`2 ** 4`

`10 / 7`

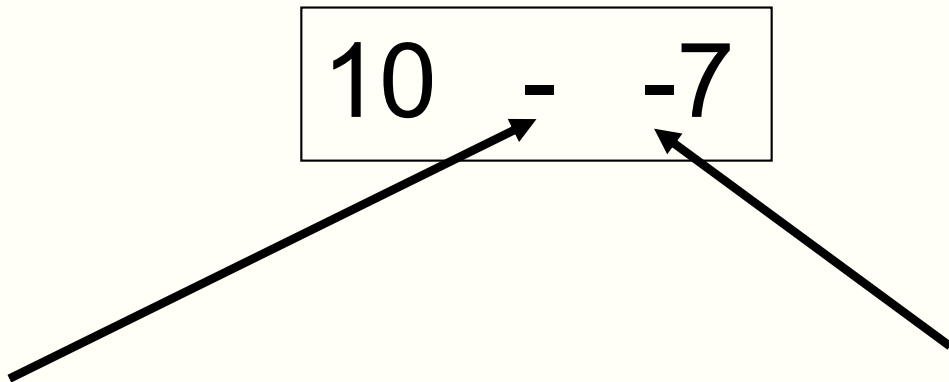

`10 // 7`

`10 % 7`

`10 - -7`

# Unary and binary operations

- + and – can be unary or binary
- For example,

$$10 - -7$$

Binary minus  
= Subtract 2 numbers

Unary minus  
= Negative sign

# Precedence

- You can use the arithmetic operators to calculate complicated expressions
- You can type:  $1 + 2 * 3 - 4$ 
  - Should this be 3 or 5?
- The computers evaluate arithmetic expressions according to the rule of precedence

# Precedence

- When evaluating arithmetic expressions, order of evaluating operations determined by ***precedence***

Operator
( )
**
+ - (unary: sign)
* / % //
+ - (binary)

Higher precedence

Lower precedence

- You do not need to memorise this. Look it up when you need. We will give this to you in the exam.

# Evaluating Expressions – Rules of Precedence

- When evaluating expressions, operations of higher precedence are performed before those of lower precedence

$$2 + 3 * 4 = 2 + (3 * 4) = 14$$

- If there are multiple operations with the same precedence

- Case 1: Multiple \*\*. Evaluate from right to left

- Example:  $4 ** 3 ** 2 = 4 ** (3 ** 2) = 262144$

- Case 2: Other operators. Evaluate from left to right

- Example:  $30 // 4 \% 2 = (30 // 4) \% 2 = 7 \% 2 = 1$

- If unsure, use parentheses or test using a simple expression

# Quiz:

- You want to calculate:

$$\frac{20}{5 \times 2}$$

- Which one can you **not** use?
  - $20 / 5 / 2$
  - $20 / 5 * 2$
  - $20 / (5 * 2)$

# Quiz

- What is `-2**2` in Python?
  - a) 4      i.e. `(-2)**2`
  - b) -4     i.e. `-(2**2)`

Operator
( )
**
+ - (unary: sign)
* / % //
+ - (binary)

Higher precedence

Lower precedence

# An exception to the rule

- If a unary – or + is to the right of \*\*, then the unary is evaluated first
- $10^{**-2} = 0.01$

# Variables and the assignment operator

- Type the following at the prompt and enter

```
In [9]: y = 5
```

- You can use `y` again to do computation

```
In [9]: y = 5
```

```
In [10]: 7 * y  
Out [10]: 35
```

```
In [11]: y / 2  
Out [11]: 2.5
```

```
In [12]: y  
Out [12]: 5
```

- We say we *assign* the value of 5 to the *variable* named `y`
- We call `=` the assignment operator
- Each line of instructions is a Python *statement*

# Programming element: Variables

- Variables are stored in computer memory
- A variable has a name and a value
- A mental picture is:

Variable name

Value of variable

A program manipulates variables to achieve its goal

Note: This is a simplified view. We will introduce the more accurate view later in the course.

# Expressions of variables

- You can combine variables in an expression
- Try this in the console:

```
In [24]: b = 2; c = 5; d = 10;
```

```
In [25]: f = (d/c)**b
```

```
In [26]: f
```

```
Out [26]: 4.0
```

```
In [27]: d = c**b
```

```
In [28]: d
```

```
Out [28]: 25
```

Old value of the variable d is overwritten

# Execution of arithmetic expressions

- Variables are stored in memory

Name of variables	Value of variables
b	2
c	5
d	10

```
d = c ** b
```

- Look up the values of **c** and **b**
- Compute **c** to the power of **b**
- Store the result in the memory for **d**
  - Since the value of **d** was 10 before executing  $d = c ** b$ , the value of **d** is overwritten and has become 25

# Assignment errors

You must assign a value to a variable before using it

```
In [32]: x - 6  
Traceback (most recent call last):
```

```
File "<ipython-input-32-86a84d68a48a>", line 1, in <module>  
    x - 6
```

**NameError: name 'x' is not defined**

```
In [31]: c**b = d  
File "<ipython-input-31-86a84d68a48a>", line 1, in <module>  
    c**b = d  
          ^
```

Order is important.  
variable\_name = expression

**SyntaxError: can't assign to operator**

# Variable names are case sensitive / debugging

```
In [100]: num = 2.15
```

```
In [101]: Num
```

```
Traceback (most recent call last):
```

```
File "<ipython-input-101-0b87731cbe51>", line 1, in <module>  
    Num
```

```
NameError: name 'Num' is not defined
```

- You should read the error message and try to understand what it means so that you can fix your own code later on
  - Programmers use the term **debugging** to mean fixing the code. See below for a discussion on the origin of the term and a picture of the moth which apparently stopped a computer program from its execution
  - <https://en.wikipedia.org/wiki/Debugging>
- Don't get upset if you get bugs in your code. It's a fact of life in computer programming. What is important is you learn how to debug.

# Don't interpret assignment as equal sign

- In mathematics, the expression  $x = x + 10$  is a contradiction
- In computer programming,  $=$  is the assignment operator, so  $x = x + 10$  means the following operations

```
In [34]: x = 7
```

```
In [35]: x = x + 10
```

```
In [36]: x  
Out [36]: 17
```

Take the value of the variable  $x$  (which is 7), add 10 to it and assign the result (which is 17) to the variable  $x$

# Quiz

- What is the value of the variable x after executing the following statements?

```
x = 10
```

```
x = x + 2
```

```
x = x + 2
```

```
x = x + 2
```

# Try yourselves

- You can also try these

$$x = 10$$

$$x = x * x$$

$$x = x \% 3$$

$$x = 2 / (x+7)$$

# Numbers and text

- Computers can handle numbers
  - Engineering data are often in numbers
  - Data processing is important in engineering
  - Numbers can also be used to represent
    - Images: Photos, X-ray images, medical images
    - Videos, music, speeches etc.
- Computers can also handle text
  - Data can also be in text

# Strings

- In Python, text is represented as strings
- Strings are always enclosed within a pair of matching single quotes or double quotes

# Strings: examples

```
In [6]: s = 'U'
```

```
In [7]: s
```

```
Out[7]: 'U'
```

```
In [8]: my_uni = 'UNSW'
```

```
In [9]: my_uni
```

```
Out[9]: 'UNSW'
```

```
In [10]: liar = 'He said that he was born on 29/02/2003. What a liar!'
```

```
In [11]: liar
```

```
Out[11]: 'He said that he was born on 29/02/2003. What a liar!'
```

- The variable `s` is a string of one character
- The variable `my_uni` is a string with 4 characters

# String manipulations

- You can
  - Concatenate strings using +
  - Repeat strings using \*

```
In [15]: str1 = 'He is a '; str2 = 'great violinist'
```

```
In [16]: str3 = str1 + str2
```

```
In [17]: str3
```

```
Out[17]: 'He is a great violinist'
```

- Try the following yourselves

```
In [19]: num_ten = 10; 'This is ' + 'so ' * num_ten + 'yummy!'
```

# Limitation of the console

- You have used the console to
  - Assign variables
  - Perform some simple computation
  - Manipulate strings
- The console is good for testing one or few lines of statements
- A more powerful method is to put the Python statements into a file, or a Python program

# Program to convert Fahrenheit to Celsius

- We will write a program to convert a temperature  $F$  in Fahrenheit to its equivalent temperature  $C$  in Celsius
- The temperatures  $F$  and  $C$  are related by

$$(F - 32) \frac{5}{9}$$

- We will develop the program step by step
- We will type the program using the editor in Spyder

# The Spyder editor

New file

Save file

Run file

Start typing in program here

# F to C conversion (version 1)

```
9 temp_fahrenheit = 80
10
11 temp_celsius = (temp_fahrenheit - 32) * (5/9)
12
13 print(temp_fahrenheit, ' in F = ', temp_celsius, ' in C')
```

- Tips:
  - Spyder gives a list of possible completions
  - The Tab key can complete variable name for you
- After typing the program, you should save it:
  - Do give the program a meaningful name.
  - Organise files using folders
  - Note that Python programs have the extension .py
  - Don't forget to save the file regularly when you work on Spyder
- You can run the program using the run button 
- Results will be displayed in the console

# The print function

```
9 temp_fahrenheit = 80
10
11 temp_celsius = (temp_fahrenheit - 32) * (5/9)
12
13 print(temp_fahrenheit, ' in F = ', temp_celsius, ' in C')
```

- **print** is a function in Python to display results
- Any text within single quotes will be displayed as is
  - You can also use double quotes. They are strings.
- If **print** sees a variable name, it will display the value of the variable
- The displayed output is the concatenation of the parts separated by commas

# Program execution

```
9 temp_fahrenheit = 80
10
11 temp_celsius = (temp_fahrenheit - 32) * (5/9)
12
13 print(temp_fahrenheit, ' in F = ', temp_celsius, ' in C')
```

- This program consists of 3 statements
  - At lines 9, 11 and 13
- The statements are executed in the order that they appear

# Identifiers

Words like `temp_celsius` in the example program are called **identifiers**

- Identifiers are used for names of variables
- Identifiers are sequences of letters (a-z, A-Z), digits (0-9) and underscores (\_)
- Identifier can only begin with a letter
- Examples of valid identifiers

`module1`   `x42`   `temp`   `y_origin`

**Quiz:** Which of the following identifiers are valid?

`day`   `2day`   `day_of_the_week`   `day2`   `$24`   `see-saw`

# Keywords

- Python has a number of keywords or reserved words
- You cannot use them as variable names
- Don't worry about memorising them now, you will see them a lot later on and will know them as your friends 😊

False	class	finally	is	return
None	continue	for	lambda	try
True	def	from	nonlocal	while
and	del	global	not	with
as	elif	if	or	yield
assert	else	import	pass	
break	except	in	raise	

<https://www.programiz.com/python-programming/keywords-identifier>

# Rules for choosing identifiers

- Rule 1: Must be valid
- Rule 2: Avoid keywords
- The program will run if it doesn't violate Rules 1 and 2
- Rule 3: Choose **meaningful** identifiers

# Identifier Conventions

- Identifier conventions have been devised to make programs more readable
  - Use meaningful variable names, most Python programmers use lower case words separated by underscore for readability

`temperature`      `num_count`

`mass_in_kg`      `is_within_normal_range`

- OK to use short names for minor or short-lived data

# Notes

- Software readability is an important issue. Here is a style guide to writing Python program, known as PEP8:
  - <https://www.python.org/dev/peps/pep-0008/>
  - ENGG1811 has its own style guide
- Note that for some other computer languages, programmers use camel case as the style for identifiers
  - Camel case: first word is all lower case, the first letter of subsequent words in upper case, e.g. `isWithinNormalRange`, `thisYear`

## F to C conversion (Version 2)

```
9  # The temperature in Fahrenheit to be converted
10 temp_fahrenheit = 80
11
12 # Convert to Celsius using standard formula
13 temp_celsius = (temp_fahrenheit - 32) * (5/9)
14
15 # Output the temperature in Celsius
16 print(temp_fahrenheit, 'in F = ', temp_celsius, 'in C')
```

- Comments are added to explain how a program works
  - All text after the # symbol is comment
- Comments are ignored when a program is executed
- Comments are for people to read

# F to C conversion (version 3)

```
22 # Constants
23 MELTING_POINT_FAHRENHEIT = 32
24 # Scaling factor for conversion
25 RATIO = 5/9
26
27 # The temperature in Fahrenheit to be converted
28 temp_fahrenheit = 80
29
30 # Convert to Celsius using standard formula
31 temp_celsius = (temp_fahrenheit - MELTING_POINT_FAHRENHEIT) * RATIO
32
33 # Output the temperature in Celsius
34 print(temp_fahrenheit, 'in F = ', temp_celsius, 'in C')
--
```

- Fixed or **constant** values are often required at several places in a program
- By giving a name to the constant...
  - The reader understands what the value *means*
    - for example, only hard-core physicists would recognise **1.3806503e-23** in a calculation (it's Boltzmann's constant)
- Name format convention: ALL\_CAPS
- Define the constants at the beginning of the program

# Why documenting a program

- Say, you've written a program that does some fabulous work for you. It is possible that you may need to modify it a few months later. You may have difficulty figuring out how you did it earlier if you haven't documented it
- Use Python docstrings

# Python docstring

```
3 """
4 Purpose: To convert temperature from Fahrenheit to Celsius
5
6 Author: Mary Poppins
7 Date: 3/2/18
8
9 Data Dictionary:
10     temp_fahrenheit    temperature in Fahrenheit to be converted to
11                       Celsius
12     temp_celsius      temperature in Celsius (final result)
13
14 Method:
15     Use the formula Celsius = (Fahrenheit - 32) * 5 / 9
16
17 """
```

- Docstring is enclosed with a pair of triple double quotes or triple single quotes
- Spyder typesets it in green
- The contents are comments, i.e., not executed

# Documentation

- Begin with:
  - Purpose, author, date
- Then data dictionary
  - list of variables used and how they are used
- Then problem parameter assignments if applicable
- Program description, method
  - Beware of the difference between purpose and method
  - Purpose (what?). Method (how?)
- Expectations:
  - Lab programs must be reasonably documented
  - Documentation carries marks in assignments

# Make the program more interactive

```
27 # The temperature in Fahrenheit to be converted
28 temp_fahrenheit = 80
29
30 # Convert to Celsius using standard formula
31 temp_celsius = (temp_fahrenheit - MELTING_POINT_FAHRENHEIT) * RATIO
32
33 # Output the temperature in Celsius
34 print(temp_fahrenheit, 'in F = ', temp_celsius, 'in C')
```

- We specify the temperature that we want to convert in Line 28
- We want to make the program more interactive by prompting the user to enter the temperature
- We can do this using the `input()` function
- The code is in the file `conversion_interactive_prelim.py`

# First attempt

```
27 # The temperature in Fahrenheit to be converted
28 temp_fahrenheit = input('Please enter a temperature in Fahrenheit: ')
29
30 # Convert to Celsius using standard formula
31 temp_celsius = (temp_fahrenheit - MELTING_POINT_FAHRENHEIT) * RATIO
32
33 # Output the temperature in Celsius
34 print(temp_fahrenheit, 'in F = ', temp_celsius, 'in C')
```

- Replace line 28 in `conversion_interactive_prelim.py` by the one shown above
- The expression that the user enters will be assigned to the variable `temp_fahrenheit`
- Let us run and see

# What is the error?

- To understand why there is an error. We look at the variable explorer

Name	Type	Size	Value
temp_fahrenheit	str	1	80

Help Variable explorer File explorer

- The value is 80. That seems correct.
- But, appearance can be a deception.

# Well, let's step away. You've known for a long time that a word may have multiple meanings ...

- The word python has two different meanings
- Same spelling but
  - Very different contexts
  - Very different ways of handling

Meaning 1

```
27 # The temperature in Fahrenheit to be c
28 temp_fahrenheit = 80
29
30 # Convert to Celsius using standard for
31 temp_celsius = (temp_fahrenheit - MELTI
32
33 # Output the temperature in Celsius
34 print(temp_fahrenheit, 'in F = ', temp_ce
```

Meaning 2

# What went wrong

Name	Type	Size	Value
temp_fahrenheit	str	1	80

This variable is a string

This line of code tries to subtract a number from a string

```
27 # The temperature in Fahrenheit to be converted
28 temp_fahrenheit = input('Please enter a temperature in Fahrenheit: ')
29
30 # Convert to Celsius using standard formula
31 temp_celsius = (temp_fahrenheit - MELTING_POINT_FAHRENHEIT) * RATIO
32
33 # Output the temperature in Celsius
34 print(temp_fahrenheit, 'in F = ', temp_celsius, 'in C')
```

# Data types

- Python (not the snake, in case you wonder which meaning it is 😊) defines different data types
- Different data types are handled differently
- Why data types? For error checking

```
In [7]: a = 80; s = '80';
```

```
In [8]: a + a + a
```

```
Out[8]: 240
```

```
In [9]: s + s + s
```

```
Out[9]: '808080'
```

Looks like they are the same but no!

Name	Type	Size	Value
a	int	1	80
s	str	1	80

# Python data types

<b>Data type</b>	<b>Meaning</b>
Integer	No decimal point (+/-)
Floating point	With decimal (+/-)
Complex number	
String	Text

# Python data types

```
In [19]: b = 80.0; c = complex(1,2)
```

```
In [20]: type(b)
```

```
Out[20]: float
```

```
In [21]: type(s)
```

```
Out[21]: str
```

- Can use the function `type()` to check the data type of a variable

Name	Type	Size	Value
a	int	1	80
b	float	1	80.0
c	complex	1	(1+2j)
s	str	1	80

# Data type conversion

- You can convert from one data type to another
  - `str()` converts the input to a string
  - Similarly, `int()` and `float()`

```
In [22]: s
Out[22]: '80'
```

```
In [23]: type(s)
Out[23]: str
```

```
In [24]: f = float(s)
```

```
In [25]: f * 2
Out[25]: 160.0
```

```
In [32]: p = str(f)
```

```
In [33]: p+p+p
Out[33]: '80.080.080.0'
```

```
In [34]: z1 = 80.5
```

```
In [35]: z2 = int(z1)
```

```
In [36]: z2
Out[36]: 80
```

# Fixing the program

```
27 # The temperature in Fahrenheit to be converted
28 temp_fahrenheit = float(input('Please enter a temperature in Fahrenheit: '))
29
30 # Convert to Celsius using standard formula
31 temp_celsius = (temp_fahrenheit - MELTING_POINT_FAHRENHEIT) * RATIO
32
33 # Output the temperature in Celsius
34 print(temp_fahrenheit, 'in F = ', temp_celsius, 'in C')
35
```

# Mathematical functions

- Standard Python has a limited set of maths operators: + - \* / // % \*\*
- Sometimes you want to use sin(), cos(), log(), exp(), etc.
- In Python, these operations are found in the **math** library

## Example: Solving quadratic equation

- We will write a program to solve the quadratic equation

$$ax^2 + bx + c = 0$$

- using the formula

$$\frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

- We will use a function to compute the square root from the math library

# Python code

quadratic\_prelim.py

```
36 # Import the math library – Need that for square root
37 import math
38
39 # Specify the coefficients of the quadratic equation
40 a = 2; b = 5; c = 1 # Enter the coefficients on this line
41
42 # Compute the square root of the discriminant (b**2-4*a*c)
43 root_discriminant = math.sqrt(b ** 2 - 4 * a * c)
44
45 # Compute the root
46 root1 = (-b + root_discriminant) / (2 * a)
47 root2 = (-b - root_discriminant) / (2 * a)
48
49 # Display the answers
50 print('The roots are ', root1, ' and ', root2)
```

- You must import the math library before using its functions
- Line 43 shows the usage of `math.sqrt()` which computes the square root

# The math library

- The math library also contains functions for:
  - Trigonometry and radian/degree conversion
    - Radian is assumed
  - Exponential and log
  - Etc.
- The file `math_examples.py` contains examples
  - Let us try some examples in the console
- For a complete list, see
  - <https://docs.python.org/3/library/math.html>
  - <https://www.programiz.com/python-programming/modules/math>

# Summary

- Spyder development environment
  - iConsole, editor, program execution, saving files
- Programming
  - Arithmetic operators and precedence
  - Variables and naming convention
  - Assignment operator =
  - Statements are executed one after another in a computer program
  - Writing computer programs in a file
  - Data types and their conversion
  - The math library
