Serial Communication-
SPI and I2C

Hasindu Gamaarachchi

Learning Resources

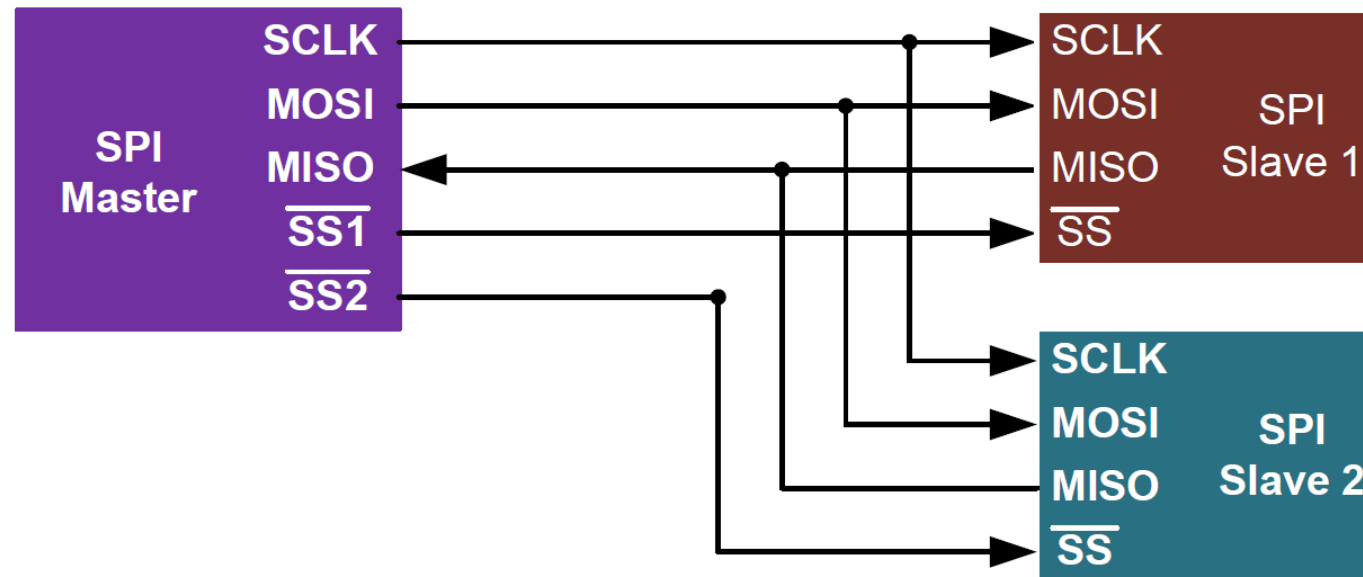

The upcoming slides are adapted from “Embedded Systems with ARM Cortex-M Microcontrollers in Assembly Language and C (Fourth Edition)” – Yifeng Zhu

- Serial communication protocols- chapter 19

Serial Peripheral Interface (SPI)

- Synchronous full-duplex communication
- Single master, multiple slaves
- Slave cannot communicate with slave directly
- Higher throughput than I2C

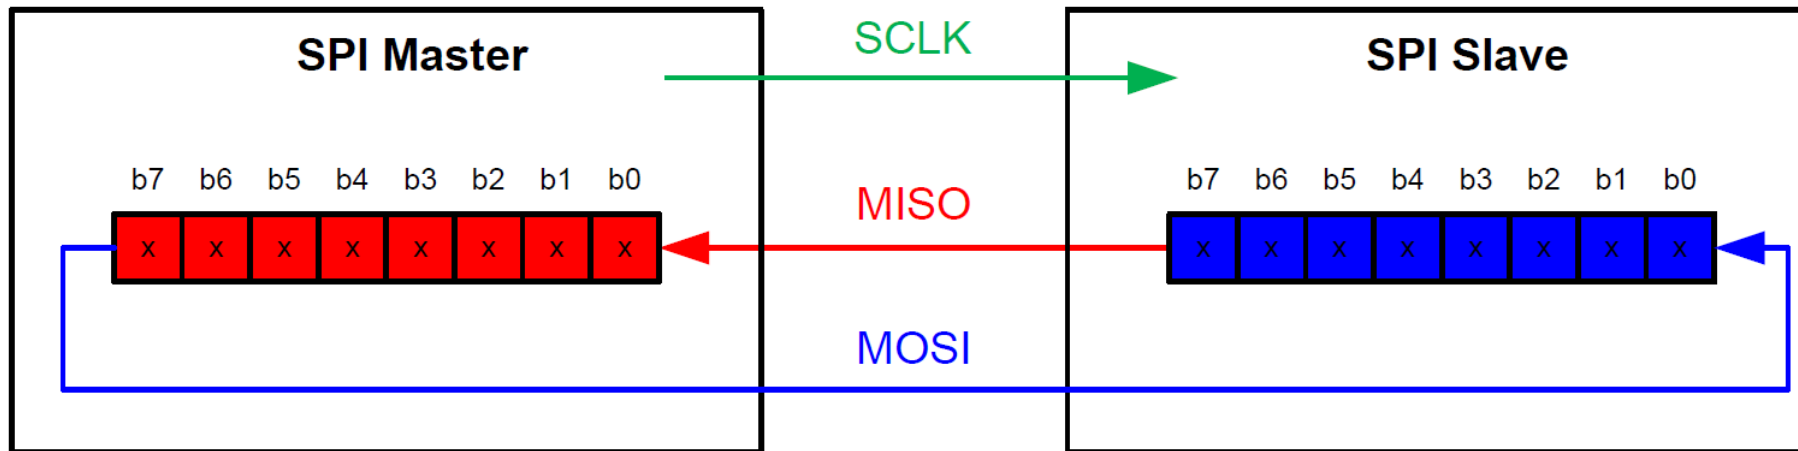

SCLK: serial clock

SS: slave select (active low)

MOSI: master out slave in

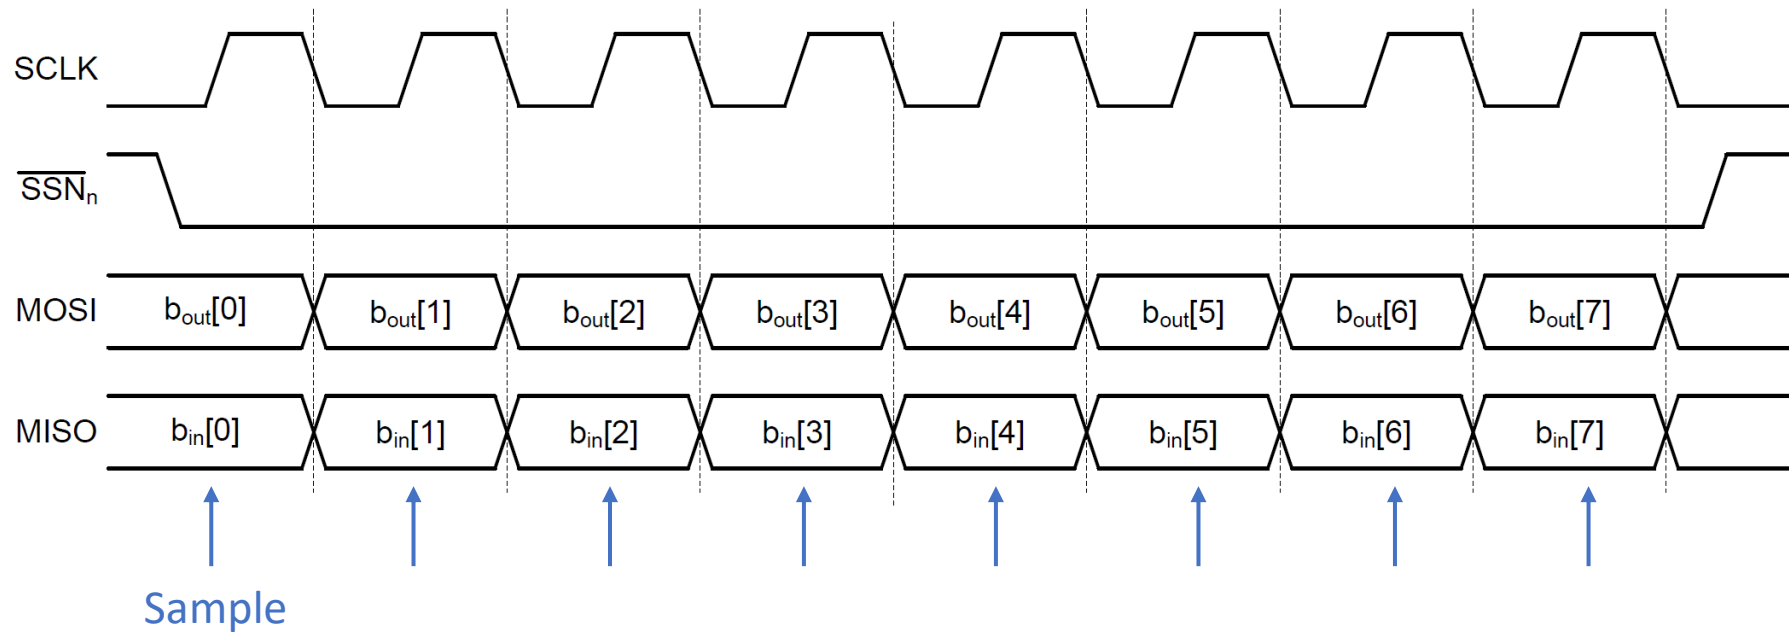

MISO: master in slave out

SPI Synchronous Data Exchange

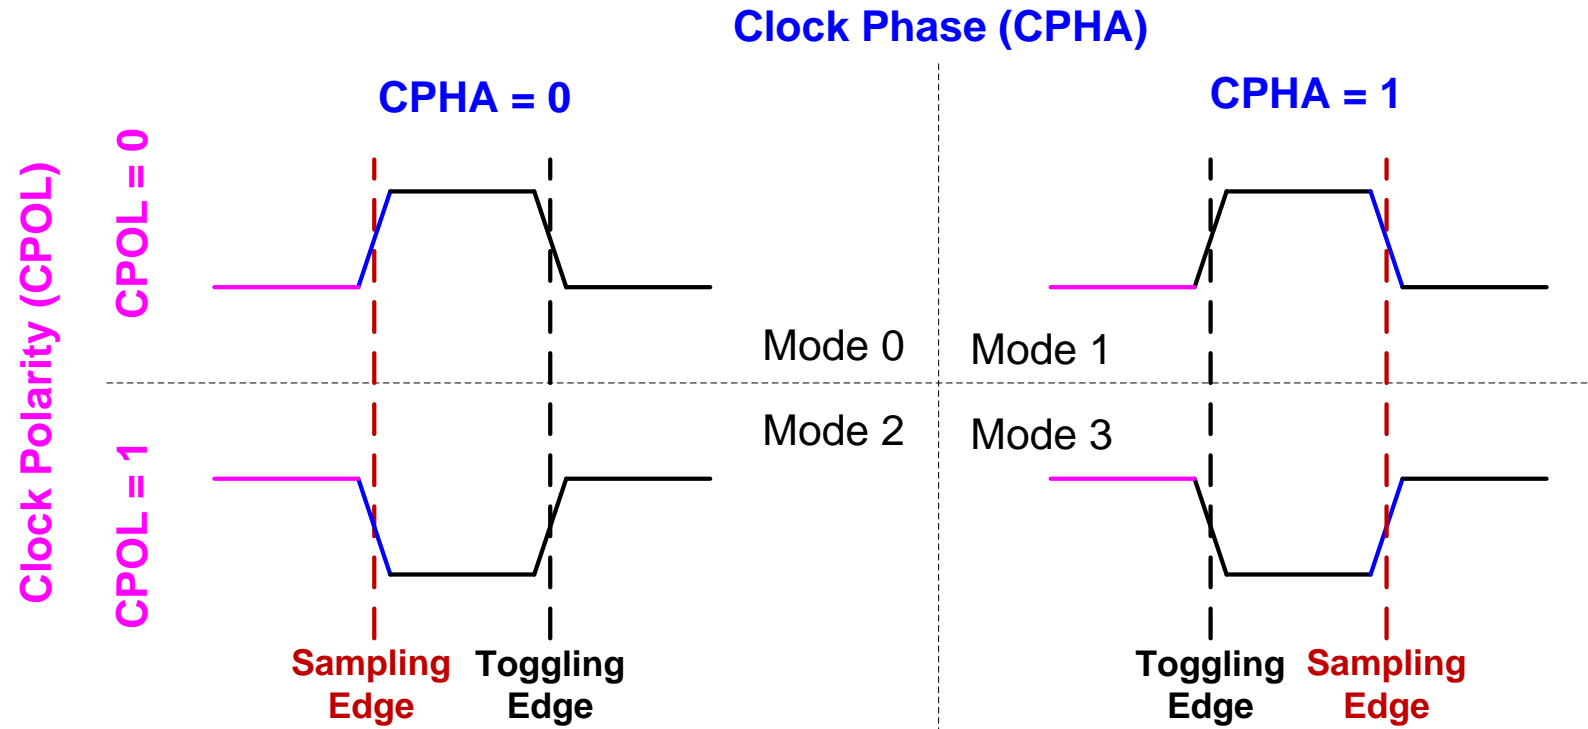

- Master has to provide clock to slave
- *Synchronous exchange*
 - Master shift out a bit to slave, and shifts in a bit from slave.
- Only master can start the data transfer.

SPI Timing Diagram

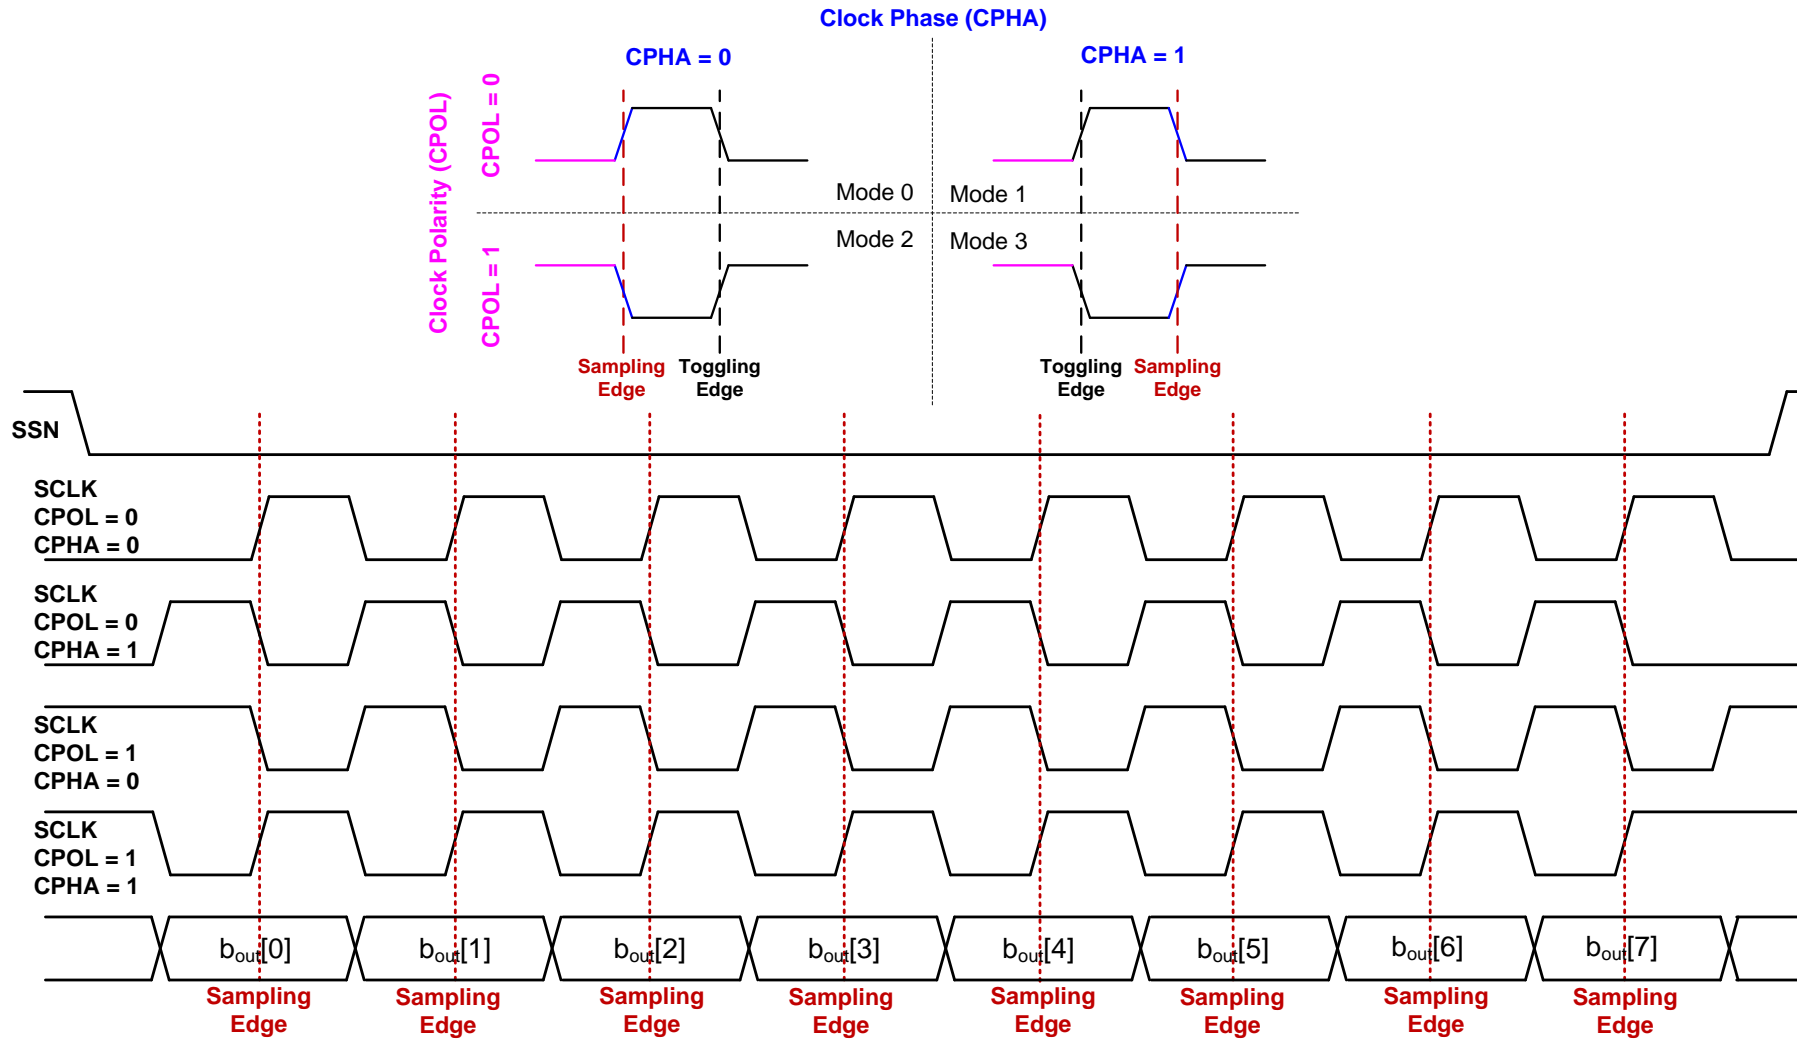

SPI Clock Phase and Polarity

- Combination of CPOL and CPHA determines the clock edge for transmitting and receiving.
- CPOL = 0 → SCLK is pushed to low during idle. Otherwise, pulled to high during idle.
- CPHA = 0 → the first clock transition (either rising or falling) is the first data capture edge. Otherwise, the second clock transition is the first data capture edge.

Inter-Integrated Circuit (I2C)

- Designed for low-cost, medium data rate applications by Philips in the early 1980's
 - Original purpose: connect a CPU to peripheral chips in a TV-set
 - Today: a de-facto standard for 2-wire communications
 - Since October 10, 2006, no licensing fees are required to implement the I²C protocol. However, fees are still required to obtain I²C slave addresses allocated by NXP (acquired Philips).
- Characteristics
 - Serial, byte-oriented
 - Multi-master, multi-slave
 - Two bidirectional open-drain lines, plus ground
 - Serial Data Line (SDA)
 - Serial Clock Line (SCL)
 - SDA and SCL need to pull up with resistors

Inter-Integrated Circuit (I2C)

- Up to 100 kbit/s in the standard mode, up to 400 kbit/s in the fast mode, and up to 3.4 Mbit/s in the high-speed mode.
- SDA and SCL have to be open-drain
- Each Device has a unique address (7, 10 or 16 bits). Address 0 used for broadcast
- STM32L's internal pull-up is too weak (internal 100K Ω)
- External pull-up (4.7 k Ω for low speed, 3 k Ω for standard mode, and 1 k Ω for fast mode).

Timing Diagram

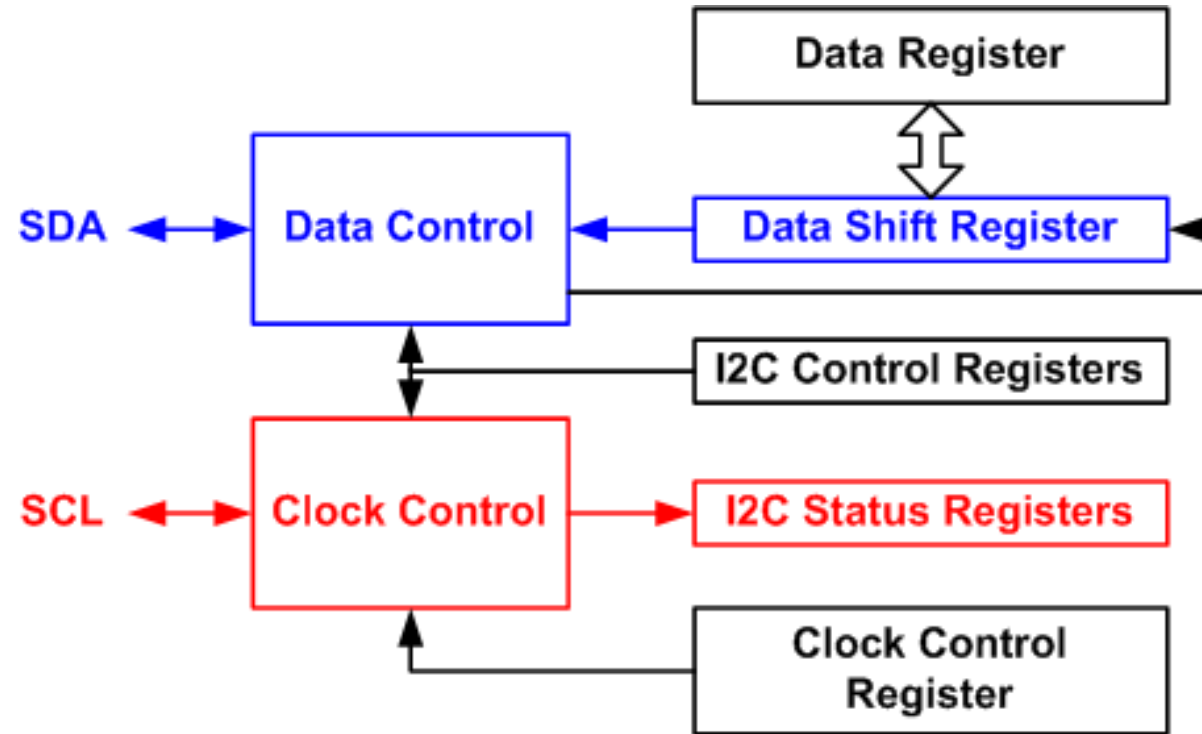

- A **START** condition is a high-to-low transition on SDA when SCL is high.
- A **STOP** condition is a low to high transition on SDA when SCL is high.
- The address and the data bytes are sent most significant bit first.
- Master generates the clock signal and sends it to the slave during data transfer
- Data on SDA can be changed only when SCL is low.

Working Modes

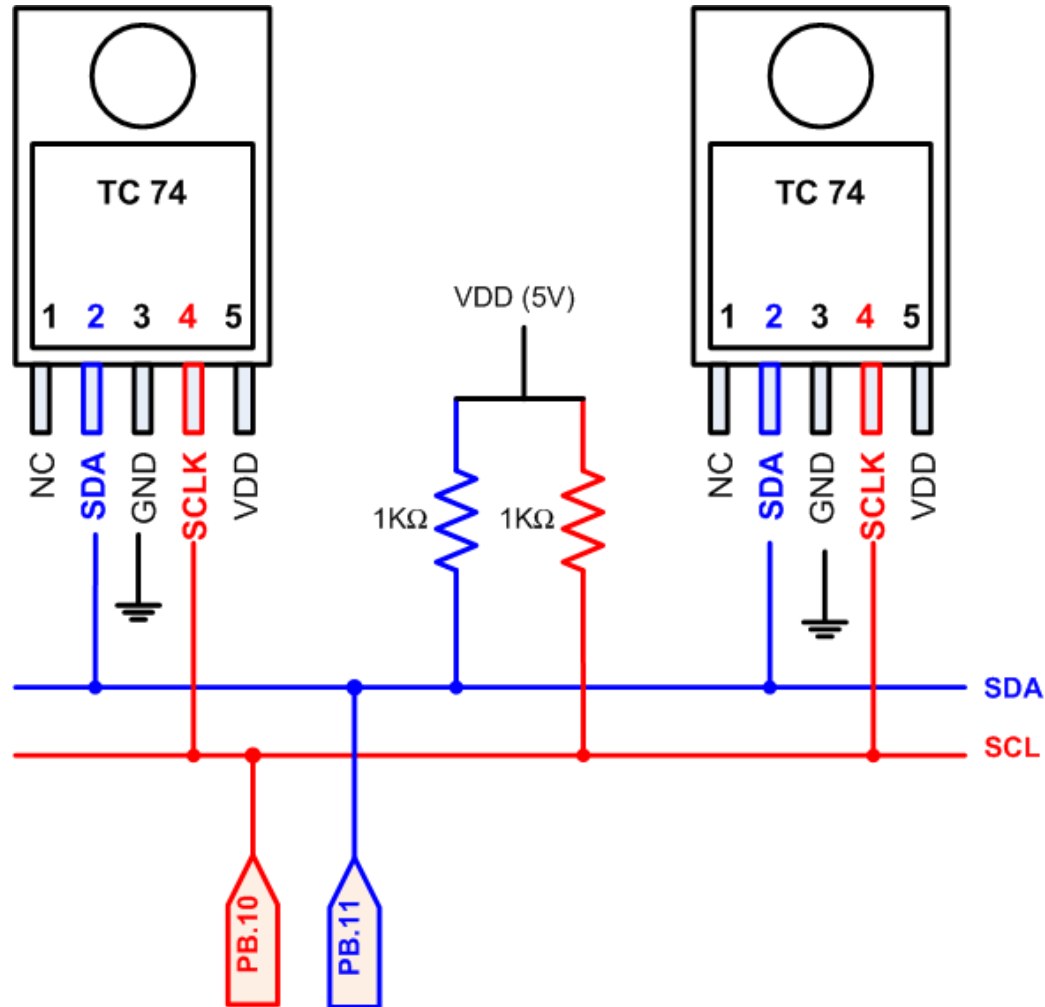

- Master-sender
 - Master issues START and ADDRESS, and then transmits data to the addressed slave device
- Master-receiver
 - Master issues START and ADDRESS, and receives data from the addressed slave device
- Slave-sender
 - Master issues START and the ADDRESS of the slave, and then the slave sends data to the master
- Slave-receiver
 - Master issues START and the ADDRESS of the slave, and then the slave receives data from the master.

STM32L I2C Module

- During sending, the I²C hardware automatically sets the **TxE flag** in the status register if an acknowledge pulse is received from the slave.
- During receiving, the I²C hardware then automatically sets the **RxNE flag** in the status register if a byte has been successfully received.

SPI vs I2C

- SPI by Motorola and I2C by Philips
- Both are synchronous protocols for short distance communications
- Generally, operates on 3.3 V or 5V

	SPI	I2C
Advantages	<ul style="list-style-type: none">• Faster speed. Can be 10 Mbps or more.• Full duplex	<ul style="list-style-type: none">• Simplicity. Commonly used as a 2-wire bus.• Adding new slave is easy
