

# 12. Exponential Time Hypothesis

## COMP6741: Parameterized and Exact Computation

Serge Gaspers

Semester 2, 2015

### Contents

1	SAT and k-SAT	1
2	Subexponential time algorithms	2
3	ETH and SETH	2
4	Algorithmic lower bounds based on ETH	2
5	Algorithmic lower bounds based on SETH	3
6	Further Reading	4

## 1 SAT and k-SAT

### SAT

#### SAT

Input: A propositional formula  $F$  in conjunctive normal form (CNF)  
Parameter:  $n = |\text{var}(F)|$ , the number of variables in  $F$   
Question: Is there an assignment to  $\text{var}(F)$  satisfying all clauses of  $F$ ?

#### k-SAT

Input: A CNF formula  $F$  where each clause has length at most  $k$   
Parameter:  $n = |\text{var}(F)|$ , the number of variables in  $F$   
Question: Is there an assignment to  $\text{var}(F)$  satisfying all clauses of  $F$ ?

### Example:

$$(x_1 \vee x_2) \wedge (\neg x_2 \vee x_3 \vee \neg x_4) \wedge (x_1 \vee x_4) \wedge (\neg x_1 \vee \neg x_3 \vee \neg x_4)$$

### Algorithms for SAT

- Brute-force:  $O^*(2^n)$
- ... after > 50 years of SAT solving (SAT association, SAT conference, JSAT journal, annual SAT competitions, ...)
- fastest known algorithm for SAT:  $O^*(2^{n \cdot (1 - 1/O(\log m/n))})$ , where  $m$  is the number of clauses [Calabro, Impagliazzo, Paturi, 2006] [Dantsin, Hirsch, 2009]
- However: no  $O^*(1.9999^n)$  time algorithm is known

- fastest known algorithms for 3-SAT:  $O^*(1.3071^n)$  randomized [Hertli, 2014] and  $O^*(1.3303^n)$  deterministic [Makino, Tamaki, Yamamoto, 2013]
- Could it be that 3-SAT cannot be solved in  $2^{o(n)}$  time?
- Could it be that SAT cannot be solved in  $O^*((2 - \epsilon)^n)$  time for any  $\epsilon > 0$ ?

## 2 Subexponential time algorithms

### NP-hard problems in subexponential time?

- Are there any NP-hard problems that can be solved in  $2^{o(n)}$  time?
- **Yes.** For example, INDEPENDENT SET is NP-complete even when the input graph is planar (can be drawn in the plane without edge crossings). Planar graphs have treewidth  $O(\sqrt{n})$  and tree decompositions of that width can be found in polynomial time (“Planar separator theorem” [Lipton, Tarjan, 1979]). Using a tree decomposition based algorithm, INDEPENDENT SET can be solved in  $2^{O(\sqrt{n})}$  time on planar graphs.

## 3 ETH and SETH

**Definition 1.** For each  $k \geq 3$ , define  $\delta_k$  to be the infimum<sup>1</sup> of the set of constants  $c$  such that  $k$ -SAT can be solved in  $O^*(2^{c \cdot n})$  time.

**Conjecture 2** (Exponential Time Hypothesis (ETH)).  $\delta_3 > 0$ .

**Conjecture 3** (Strong Exponential Time Hypothesis (SETH)).  $\lim_{k \rightarrow \infty} \delta_k = 1$ .

**Notes:** (1) ETH  $\Rightarrow$  3-SAT cannot be solved in  $2^{o(n)}$  time. SETH  $\Rightarrow$  SAT cannot be solved in  $O^*((2 - \epsilon)^n)$  time for any  $\epsilon > 0$ .

## 4 Algorithmic lower bounds based on ETH

- Suppose ETH is true
- Can we infer lower bounds on the running time needed to solve other problems?
- Suppose there is a polynomial-time reduction from 3-SAT to a graph problem  $\Pi$ , which constructs an equivalent instance where the number of vertices of the output graph equals the number of variables of the input formula,  $|V| = |\text{var}(F)|$ .
- Using the reduction, we can conclude that, if  $\Pi$  has an  $O^*(2^{o(|V|)})$  time algorithm, then 3-SAT has an  $O^*(2^{o(|\text{var}(F)|)})$  time algorithm, contradicting ETH.
- Therefore, we conclude that  $\Pi$  has no  $O^*(2^{o(|V|)})$  time algorithm unless ETH fails.

### Sparsification Lemma

**Issue:** Many reductions from 3-SAT create a number of vertices / variables / elements that are related to the number of *clauses* of the 3-SAT instance.

**Theorem 4** (Sparsification Lemma, [Impagliazzo, Paturi, Zane, 2001]). *For each  $\epsilon > 0$  and positive integer  $k$ , there is a  $O^*(2^{\epsilon \cdot n})$  time algorithm that takes as input a  $k$ -CNF formula  $F$  with  $n$  variables and outputs an equivalent formula  $F' = \bigvee_{i=1}^t F_i$  that is a disjunction of  $t \leq 2^{\epsilon n}$  formulas  $F_i$  with  $\text{var}(F_i) = \text{var}(F)$  and  $|\text{cla}(F_i)| = O(n)$ .*

<sup>1</sup>The infimum of a set of numbers is the largest number that is smaller or equal to each number in the set. E.g., the infimum of  $\{\epsilon \in \mathbb{R} : \epsilon > 0\}$  is 0.

### 3-SAT with a linear number of clauses

**Corollary 5.**  $ETH \Rightarrow 3\text{-SAT}$  cannot be solved in  $O^*(2^{o(n+m)})$  time where  $m$  denotes the number of clauses of  $F$ .

**Observation:** Let  $A, B$  be parameterized problems and  $f, g$  be non-decreasing functions. Suppose there is a polynomial-parameter transformation from  $A$  to  $B$  such that if the parameter of an instance of  $A$  is  $k$ , then the parameter of the constructed instance of  $B$  is at most  $g(k)$ . Then an  $O^*(2^{o(f(k))})$  time algorithm for  $B$  implies an  $O^*(2^{o(f(g(k)))})$  time algorithm for  $A$ .

### More general reductions are possible

**Definition 6** (SERF-reduction). A *SubExponential Reduction Family* from a parameterized problem  $A$  to a parameterized problem  $B$  is a family of *Turing reductions* from  $A$  to  $B$  (i.e., an algorithm for  $A$ , making queries to an *oracle* for  $B$  that solves any instance for  $B$  in constant time) for each  $\varepsilon > 0$  such that

- for every instance  $I$  for  $A$  with parameter  $k$ , the running time is  $O^*(2^{\varepsilon k})$ , and
- for every query  $I'$  to  $B$  with parameter  $k'$ , we have that  $k' \in O(k)$  and  $|I'| = |I|^{O(1)}$ .

**Note:** If  $A$  is SERF-reducible to  $B$  and  $A$  has no  $2^{o(k)}$  time algorithm, then  $B$  has no  $2^{o(k')}$  time algorithm.

### Vertex Cover has no subexponential algorithm

Polynomial-parameter transformation from 3-SAT.

For simplicity, assume all clauses have length 3.

3-CNF Formula  $F = (u \vee v \vee \neg y) \wedge (\neg u \vee y \vee z) \wedge (\neg v \vee w \vee x) \wedge (x \vee y \vee \neg z)$

For a 3-CNF formula with  $n$  variables and  $m$  clauses, we create a VERTEX COVER instance with  $|V| = 2n + 3m$  and  $k = n + 2m$ .

**Theorem 7.**  $ETH \Rightarrow \text{VERTEX COVER}$  has no  $2^{o(|V|)}$  time algorithm.

**Theorem 8.**  $ETH \Rightarrow \text{VERTEX COVER}$  has no  $2^{o(k)}$  time algorithm.

## 5 Algorithmic lower bounds based on SETH

### Hitting Set

**Recall:** A *hitting set* of a set system  $\mathcal{S} = (V, H)$  is a subset  $X$  of  $V$  such that  $X$  contains at least one element of each set in  $H$ , i.e.,  $X \cap Y \neq \emptyset$  for each  $Y \in H$ .

#### elts-HITTING SET

Input: A set system  $\mathcal{S} = (V, H)$  and an integer  $k$   
 Parameter:  $n = |V|$   
 Question: Does  $\mathcal{S}$  have a hitting set of size at most  $k$ ?

### SETH-lower bound for Hitting Set

CNF Formula  $F = (u \vee v \vee \neg y) \wedge (\neg u \vee y \vee z) \wedge (\neg v \vee w \vee x) \wedge (x \vee y \vee \neg z)$

Incidence graph of equivalent Hitting Set instance:

For a CNF formula with  $n$  variables and  $m$  clauses, we create a HITTING SET instance with  $|V| = 2n$  and  $k = n$ .

**Theorem 9.** *SETH*  $\Rightarrow$  HITTING SET has no  $O^*((2 - \varepsilon)^{|V|/2})$  time algorithm for any  $\varepsilon > 0$ .

**Note:** With a more ingenious reduction, one can show that HITTING SET has no  $O^*((2 - \varepsilon)^{|V|})$  time algorithm for any  $\varepsilon > 0$  under SETH.

### Exercise

A *dominating set* of a graph  $G = (V, E)$  is a set of vertices  $S \subseteq V$  such that  $N_G[S] = V$ .

#### vertex-DOMINATING SET

Input: A graph  $G = (V, E)$  and an integer  $k$

Parameter:  $n = |V|$

Question: Does  $G$  have a dominating set of size at most  $k$ ?

- Prove that ETH  $\Rightarrow$  vertex-DOMINATING SET has no  $2^{o(n)}$  time algorithm.
