# Prolog

---

- Compound terms can contain other compound terms
- A compound term can contain the same kind of term, i.e., it can be recursive:  
`tree(tree(empty, jack, empty), fred, tree(empty, jill, empty))`
- “empty” is an arbitrary symbol use to represent the empty tree
- A structure like this could be used to represent a binary tree that looks like:

# Binary Trees

---

- A **binary tree** is either empty or it is a structure that contains data and left and right subtrees which are also binary trees
- To test if some datum is in the tree:

```
in_tree(X, tree(_, X, _)).  
in_tree(X, tree(Left, Y, _) :-  
    X \= Y,  
    in_tree(X, Left).  
in_tree(X, tree(_, Y, Right) :-  
    X \= Y,  
    in_tree(X, Right).
```

# The Size of a Tree

---

- `tree_size(empty, 0).`  
`tree_size(tree(Left, _, Right), N) :-`  
    `tree_size(Left, LeftSize),`  
    `tree_size(Right, RightSize),`  
    `N is LeftSize + RightSize + 1.`
- The size of the empty tree is 0
- The size of a non-empty tree is the size of the left subtree plus the size of the right subtree plus one for the current node

# Lists

---

- A **list** may be **nil** or it may be a term that has a **head** and a **tail**. The tail is another list.
- A list of numbers, [1, 2, 3] can be represented as:

```
list(1, list(2, list(3, nil)))
```

- Since lists are used so often, Prolog has a special notation:

```
[1, 2, 3] = list(1, list(2, list(3, nil)))
```

## Examples of Lists

---

$[X, Y, Z] = [1, 2, 3]?$  Unify the two terms on either side of the equals sign

$X = 1$

$Y = 2$

$Z = 3$

Variables match terms in corresponding positions

$[X|Y] = [1, 2, 3]?$

$X = 1$

$Y = [2, 3]$

The head and tail of a list are separated by using ‘|’ to indicate that the term following the bar should unify with the tail of the list

$[X|Y] = [1]?$

$X = 1$

$Y = []$

The empty list is written as ‘[]’

The end of a list is usually ‘[]’

## More list examples

---

$[X, Y|Z] = [\text{fred}, \text{jim}, \text{jill}, \text{mary}]?$  There must be at least two elements in the list on the right

$X = \text{fred}$

$Y = \text{jim}$

$Z = [\text{jill}, \text{mary}]$

$[X|Y] = [[\text{a}, \text{f}(\text{e})], [\text{n}, \text{b}, [2]]]?$  The right hand list has two elements:

$X = [\text{a}, \text{f}(\text{e})]$

$Y = [[\text{n}, \text{b}, [2]]]$

$[\text{a}, \text{f}(\text{e})] [\text{n}, \text{b}, [2]]$

Y is the tail of the list,

$[\text{n}, \text{b}, [2]]$  is just one element

# List Membership

---

```
member(X, [X|_]).  
member(X, [_|Y]) :-  
    member(X, Y).
```

- Rules about writing recursive programs:
  - ▶ Only deal with one element at a time
  - ▶ Believe that the recursive program you are writing has already been written and works
  - ▶ Write definitions, not programs

# Appending Lists

---

- A commonly performed operation on lists is to append one list to the end of another (or, concatenate two lists), e.g.,

```
append([1, 2, 3], [4, 5], [1, 2, 3, 4, 5]).
```

- Start planning by considering the simplest case:

```
append([], [1, 2, 3], [1, 2, 3]).
```

- Clause for this case:

```
append([], L, L).
```

# Appending Lists

---

- Next case:

```
append([1], [2], [1, 2]).
```

- Since `append([], [2], [2])`:

```
append([H|T1], L, [H|T2]) :- append(T1, L, T2).
```

- Entire program is:

```
append([], L, L).  
append([H|T1], L, [H|T2]) :-  
    append(T1, L, T2).
```

# Reversing Lists

---

- `rev([1, 2, 3], [3, 2, 1]).`
- Start planning by considering the simplest case:  
`rev([], []).`
- Note:  
`rev([2, 3], [3, 2]).`  
and  
`append([3, 2], [1], [3, 2, 1]).`

# Reversing Lists

---

- Entire program is:

```
rev([], []).  
rev([A|B], C) :-  
    rev(B, D),  
    append(D, [A], C).
```

# An Application of Lists

---

- Find the total cost of a list of items:

```
cost(flange, 3).  
cost(nut, 1).  
cost(widget, 2).  
cost(splice, 2).
```

- We want to know the total cost of [flange, nut, widget, splice]

```
total_cost([], 0).  
total_cost([A|B], C) :-  
    total_cost(B, B_cost),  
    cost(A, A_cost),  
    C is A_cost + B_cost.
```
