## COMP9024: Data Structures and Algorithms

## Randomized Algorithms

## Contents

- Randomized Algorithm
- Quick Selection
- Skip Lists

## Randomized Algorithm (1/2)

- A randomized algorithm is an algorithm that employs a degree of randomness as part of its logic.
- The algorithm typically uses uniformly random bits as an auxiliary input to guide its behaviour, in the hope of achieving good performance in the average case over all possible choices of random bits.
- The performance of a randomized algorithm is a random variable determined by the random bits.
- The worst-case performance is typically bad with a very small probability but the average performance can be good.
- Two categories: Las Vegas algorithm and Monte Carlo algorithm

## Randomized Algorithm (2/2)

- Las Vegas algorithm
- A Las Vegas algorithm is a randomized algorithm that always gives correct results
- Monte Carlo algorithm
- A Monte Carlo algorithm is a randomized algorithm whose output may be incorrect with a certain (typically small) probability

## An Example (1/5)

- Given an unsorted list where half of the elements have a key k 1 and the other half have a key k 2 , find an element in the list with key k1.

## An Example (2/5)

## - Las Vegas algorithm

Algorithm findKey(L, k1)
Input: list L, key k1
Output: an element in L with key k1
\{
repeat
randomly select $\mathrm{e} \in \mathrm{L}$;
until key(e)=k1;
return e;
\}

## An Example (3/5)

Analysis:

- Probability of success: 1
- The number of iterations varies and can be arbitrarily large, but the expected number of iterations is:

$$
\lim _{n \rightarrow \infty} \sum_{i=0}^{n} \frac{i}{2^{i}}=2
$$

- The expected time complexity is $\mathrm{O}(1)$

## An Example (4/5)

- Monte Carlo algorithm

Algorithm findKey(L, k1)
Input: list L, key k1
Output: an element in L with key k1
\{
i=0;
repeat
randomly select $e \in L$;
i++;
until $\operatorname{key}(\mathrm{e})=\mathrm{k} 1$ or $\mathrm{i}=\mathrm{m}$; return e;
$\}$

## An Example (5/5)

## Analysis:

- After k iterations, the probability of finding an element with key k 1 is $1-\left(\frac{1}{2}\right)^{k}$
- Time complexity is $\mathrm{O}(1)$ but its does not guarantee success

# Quick Selection 

## The Selection Problem

Given an integer $k$ and $n$ elements $x_{1}, x_{2}, \ldots, x_{n}$, taken from a total order, find the $k$-th smallest element in this set.
Of course, we can sort the set in $O(n \log n)$ time and then index the $k$-th element.

$$
\mathrm{k}=3 \quad 749 \underline{6} 2 \rightarrow 24 \underline{6} 79
$$

Can we solve the selection problem faster?

## Quick-Select (1/2)

Quick-select is a randomized selection algorithm based on the prune-and-search paradigm:

- Prune: pick a random element $\boldsymbol{x}$ (called pivot) and partition $S$ into
- $L$ elements less than $\boldsymbol{x}$
- $\boldsymbol{E}$ elements equal $\boldsymbol{x}$
- $\boldsymbol{G}$ elements greater than $\boldsymbol{x}$
- Search: depending on k, either $\quad \boldsymbol{k} \leq|\boldsymbol{L}|$ answer is in $\boldsymbol{E}$, or we need to recurse in either $\boldsymbol{L}$ or $\boldsymbol{G}$

## Quick-Select (2/2)

## Algorithm quickSelect(S, k)

Input Sequence $S$ of $|S|$ comparable elements and an integer $\boldsymbol{k}$ in $[1,|S|]$
Output The $\boldsymbol{k}$-th smallest element of $S$
\{ if $|S|=1$
return the (first) element of $S$;
pick a random integer $i$ in $[1,|S|] ; / /|S|$ is the size of $S$;
$(\boldsymbol{L}, \boldsymbol{E}, \boldsymbol{G})=\operatorname{partition}(S, i)$;
if $\boldsymbol{k}<\boldsymbol{l}$
quickSelect(L, k);
else if $\boldsymbol{k}<=|\boldsymbol{L}|+|\boldsymbol{E}|$
return $\mathrm{S}[\mathrm{i}]$; // Each element in $\boldsymbol{E}$ is equal to $S[\mathrm{i}]$
else // Find the $\boldsymbol{k}-|\boldsymbol{L}|-|\boldsymbol{E}|$-th element in $\boldsymbol{G}$
quickSelect ( $\boldsymbol{G}, \boldsymbol{k}-|\boldsymbol{L}|-|E|)$;
\}

## Partition

## Algorithm partition(S, i)

We partition an input sequence as in the quick-sort algorithm:

- We remove, in turn, each element $y$ from $S$ and
- We insert $\boldsymbol{y}$ into $\boldsymbol{L}, \boldsymbol{E}$ or $\boldsymbol{G}$, depending on the result of the comparison with the pivot $x$
Each insertion and removal is at the beginning or at the end of a sequence, and hence takes $\boldsymbol{O}(1)$ time Thus, the partition step of quick-select takes $\boldsymbol{O}(\boldsymbol{n})$ time

Input sequence $S$, index $i$ of the pivot
Output subsequences $\boldsymbol{L}, \boldsymbol{E}, \boldsymbol{G}$ of the elements of $\boldsymbol{S}$ less than, equal to, or greater than the pivot, resp.
$\{\boldsymbol{L}, \boldsymbol{E}, \boldsymbol{G}=$ empty sequences; $\boldsymbol{x}=\boldsymbol{S}[i] ;$
while ( $\neg$ S.isEmpty () )
$\{y=S . \operatorname{remove}(S . \operatorname{first}())$;
if $(y<x)$
L.insertLast(y);
else if $(y=x)$
E.insertLast(y);
else $/ / \boldsymbol{y}>\boldsymbol{x}$
G.insertLast(y); \}
return $L, E, G$;

## Quick-Select Visualization

- An execution of quick-select can be visualized by a recursion path
- Each node represents a recursive call of quick-select, and stores $k$ and the remaining sequence

## Worst-Case Time complexity (1/3)

- What is the worst-case?
> Each time the smallest key or the largest key is selected, and thus only one element (the one with the smallest key or the one with the largest key) is excluded on each iteration
- The worst-case time complexity is
- $\mathrm{O}(\mathrm{n})+\mathrm{O}(\mathrm{n}-1)+\ldots+\mathrm{O}(2)+\mathrm{O}(1)$
$=O((n(n+1) / 2))=O\left(n^{2}\right)$

## Worst-Case Time complexity (2/3)

- What is the probability of the worst-case?
- Let $\varepsilon_{k}$ be the event that we pick the largest or smallest element when there are $k$ elements left.
- Let event $\varepsilon$ be the worst-case. We have:

$$
\varepsilon=\prod_{i=1}^{i=n} \varepsilon_{i}
$$

- What is $\mathrm{P}(\varepsilon)=\mathrm{P}\left(\prod_{i=1}^{i=n} \varepsilon_{i}\right)$ ?
- Since all $\varepsilon_{i}^{\prime}$ 's are independent, this simplifies to

$$
\mathrm{P}(\varepsilon)=\mathrm{P}\left(\prod_{i=1}^{i=n} \varepsilon_{i}\right)=\prod_{i=1}^{i=n} P\left(\varepsilon_{i}\right)
$$

## Worst-Case Time complexity (3/3)

- $P\left(\varepsilon_{1}\right)=1$.
- If $\mathrm{i}>1$, then $\mathrm{P}\left(\mathcal{E}_{\mathrm{i}}\right)=\frac{2}{i}$. Thus
$\mathrm{P}(\mathcal{E})=\prod_{i=1}^{i=n} P\left(\varepsilon_{i}\right)=\prod_{i=2}^{i=n} \frac{2}{i}=\frac{2^{n-1}}{n!}$
- if $n=31$, then $2^{n-1}<10^{10}$ and $n!\approx 8 \times 10^{33}$ $P(\varepsilon)<1 / 10^{22}$. This is extremely unlikely!

## Expected Running Time (1/2)

- Consider a recursive call of quick-select on a sequence of size $s$
- Good call: the sizes of $L$ and $G$ are each less than $3 \boldsymbol{s} / 4$
- Bad call: one of $L$ and $\boldsymbol{G}$ has size greater than $3 s / 4$

Good call

Bad call

- A call is good with probability $1 / 2$
- $1 / 2$ of the possible pivots cause good calls:

## Expected Running Time (2/2)

Probabilistic Fact \#1: The expected number of coin tosses required in order to get one head is two

- Probabilistic Fact \#2: Expectation is a linear function:
- $E(X+Y)=E(X)+E(Y)$
- $E(c X)=c E(X)$
- Let $\mathrm{T}(\mathrm{n})$ denote the expected running time of quick-select.
- By Fact \#2,
- $T(n) \leq T(3 n / 4)+b n *($ expected \# of calls for a good call)
- By Fact \#1,
- $T(n) \leq T(3 n / 4)+2 b n$
- That is, $\mathrm{T}(\mathrm{n})$ is a geometric series:
- $T(n) \leq 2 b n+2 b(3 / 4) n+2 b(3 / 4)^{2} n+2 b(3 / 4)^{3} n+\ldots$
- So $T(n)$ is $O(n)$.
- We can solve the selection problem in $O(n)$ expected time.

## Skip Lists

## What is a Skip List

- A skip list for a set $\boldsymbol{S}$ of distinct (key, element) items is a series of lists $\boldsymbol{S}_{0}, \boldsymbol{S}_{1}, \ldots, \boldsymbol{S}_{\boldsymbol{h}}$ such that
- Each list $S_{i}$ contains the special keys $+\infty$ and $-\infty$
- List $\boldsymbol{S}_{0}$ contains the keys of $\boldsymbol{S}$ in nondecreasing order
- Each list is a subsequence of the previous one, i.e.,

$$
\boldsymbol{S}_{0} \supseteq \boldsymbol{S}_{1} \supseteq \ldots \supseteq \boldsymbol{S}_{\boldsymbol{h}}
$$

- List $S_{h}$ contains only the two special keys
- We show how to use a skip list to implement the dictionary ADT

## Search

We search for a key $\boldsymbol{x}$ in a a skip list as follows:

- We start at the first position of the top list
- At the current position $\boldsymbol{p}$, we compare $\boldsymbol{x}$ with $\boldsymbol{y} \leftarrow \boldsymbol{\operatorname { l e y }}(\boldsymbol{n e x t}(\boldsymbol{p}))$

$$
\begin{aligned}
& x=y: \text { we return element }(\text { next }(p)) \\
& x>y: \text { we "scan forward" } \\
& x<y: \text { we "drop down" }
\end{aligned}
$$

- If we try to drop down past the bottom list, we return null
- Example: search for 78

## Insertion

To insert an entry $(\boldsymbol{x}, \boldsymbol{o})$ into a skip list, we use a randomized algorithm:

- We repeatedly toss a coin until we get a tail, and we denote with $\boldsymbol{i}$ the number of times the coin came up with heads
- If $\boldsymbol{i} \geq \boldsymbol{h}$, we add to the skip list new lists $\boldsymbol{S}_{\boldsymbol{h}+1}, \ldots, \boldsymbol{S}_{\boldsymbol{i + 1}}$, each containing only the two special keys
- We search for $\boldsymbol{x}$ in the skip list and find the positions $\boldsymbol{p}_{0}, \boldsymbol{p}_{1}, \ldots, \boldsymbol{p}_{i}$ of the items with largest key less than $x$ in each list $S_{0}, S_{1}, \ldots, S_{i}$
- For $\boldsymbol{j} \leftarrow 0, \ldots, \boldsymbol{i}$, we insert item $(\boldsymbol{x}, \boldsymbol{o})$ into list $\boldsymbol{S}_{\boldsymbol{j}}$ after position $\boldsymbol{p}_{\boldsymbol{j}}$
- Example: insert key 15 , with $\boldsymbol{i}=2$

## Deletion

To remove an entry with key $x$ from a skip list, we proceed as follows:

- We search for $\boldsymbol{x}$ in the skip list and find the positions $\boldsymbol{p}_{0}, \boldsymbol{p}_{1}, \ldots, \boldsymbol{p}_{i}$ of the items with key $\boldsymbol{x}$, where position $\boldsymbol{p}_{j}$ is in list $S_{j}$
- We remove positions $\boldsymbol{p}_{0}, \boldsymbol{p}_{1}, \ldots, \boldsymbol{p}_{i}$ from the lists $\boldsymbol{S}_{0}, \boldsymbol{S}_{1}, \ldots, \boldsymbol{S}_{\boldsymbol{i}}$
- We remove all but one list containing only the two special keys
- Example: remove key 34

## Implementation

- We can implement a skip list with quad-nodes
- A quad-node stores:
- entry
- link to the node prev
- link to the node next
- link to the node below
- link to the node above
- Also, we define special keys PLUS_INF and MINUS_INF, and we modify the key comparator to handle them

## Space Usage

- The space used by a skip list depends on the random bits used by each invocation of the insertion algorithm
- We use the following two basic probabilistic facts:
Fact 1: The probability of getting $i$ consecutive heads when flipping a coin is $1 / 2^{i}$
Fact 2: If each of $\boldsymbol{n}$ entries is present in a set with probability $\boldsymbol{p}$, the expected size of the set is $n \boldsymbol{p}$
- Consider a skip list with $n$ entries
- By Fact 1, we insert an entry in list $S_{i}$ with probability $1 / 2^{i}$
- By Fact 2, the expected size of list $S_{i}$ is $n / 2^{i}$
- The expected number of nodes used by the skip list is

$$
\sum_{i=0}^{h} \frac{n}{2^{i}}=n \sum_{i=0}^{h} \frac{1}{2^{i}}<2 n
$$

- Thus, the expected space usage of a skip list with $n$ items is $\boldsymbol{O}(\boldsymbol{n})$

## Height

- The running time of the search and insertion algorithms is affected by the height $\boldsymbol{h}$ of the skip list
- We show that with high probability, a skip list with $n$ items has height $\boldsymbol{O}(\log \boldsymbol{n})$
- We use the following additional probabilistic fact:
Fact 3: If each of $\boldsymbol{n}$ events has probability $\boldsymbol{p}$, the probability that at least one event occurs is at most $\boldsymbol{n p}$
- Consider a skip list with $n$ entries
- By Fact 1, we insert an entry in list $S_{i}$ with probability $1 / 2^{i}$
- By Fact 3, the probability that list $S_{i}$ has at least one item is at most $n / 2^{i}$
- By picking $\boldsymbol{i}=3 \log \boldsymbol{n}$, we have that the probability that $S_{3 \log n}$ has at least one entry is at most

$$
\boldsymbol{n} / 2^{3 \log n}=\boldsymbol{n} / \boldsymbol{n}^{3}=1 / \boldsymbol{n}^{2}
$$

- Thus a skip list with $n$ entries has height at most $3 \log n$ with probability at least $1-1 / \boldsymbol{n}^{2}$

## Search and Update Times

The search time in a skip list is proportional to

- the number of drop-down steps, plus
- the number of scan-forward steps
- The drop-down steps are bounded by the height of the skip list and thus are $\boldsymbol{O}(\log \boldsymbol{n})$ with high probability
- To analyze the scan-forward steps, we use yet another probabilistic fact:
Fact 4: The expected number of coin tosses required in order to get a tail is 2
- When we scan forward in a list, the destination key does not belong to a higher list
- A scan-forward step is associated with a former coin toss that gave a tail
- By Fact 4, in each list the expected number of scanforward steps is 2
- Thus, the expected number of scan-forward steps is $\boldsymbol{O}(\log n)$
- We conclude that a search in a skip list takes $\boldsymbol{O}(\log \boldsymbol{n})$ expected time
- The analysis of insertion and deletion gives similar results

## Summary

- Randomized algorithm
- Las Vegas algorithm
- Monte Carlo algorithm
- Randomized selection algorithm
- Skip lists
