What did we learn last lecture?

Linked Lists

- Linked List Recap
- Insertion into Lists
- Looping through Linked Lists to find specific conditions
What are we doing today?

More Linked Lists

- Linked List Removal
- Freeing our Allocated Memory
- Playing the Battle Royale game
Insertion with some conditions - recap

We can now insert into any position in a Linked List

- We can read the data in a node and decide whether we want to insert before or after it
- Let's insert our elements into our list based on alphabetical order
- We're going to use a `string.h` function, `strcmp()` for this
- `strcmp()` compares two strings, and returns
  - 0 if they're equal
  - negative if the first has a lower ascii value than the second
  - positive if the first has a higher ascii value than the second
Finding where to insert

We're going to loop through the list

- This loop assumes the list is already in alphabetical order
- Each time we loop, we're going to keep track of the previous player
- We'll test the name of each player using `strcmp()`
- We stop looping once we find the first name that's "higher" than ours
- Then we insert before that player
Finding the insertion point

Attempting to insert a player with name: "C" into a sorted list while maintaining the alphabetical order

head points at the first player

loop starts here

Insert between these two players

loop stops here
Inserting into a list Alphabetically

```c
struct player *insert_alpha(char new_name[], struct player* head) {
    struct player *previous = NULL;
    struct player *p = head;
    // Loop through the list and find the right place for the new name
    while (p != NULL && strcmp(new_name, p->name) > 0) {
        previous = p;
        p = p->next;
    }
    struct player *insert_point = insert_after(new_name, previous);
    // Return the head of the list (even if it has changed)
    if (previous == NULL) { // we inserted at the start of the list
        insert_point->next = p;
        return insert_point;
    } else {
        return head;
    }
}
```
Removing a player

If we want to remove a specific player, given their name

- We need to look through the list and see if a player name matches the one we want to remove
- To remove, we'll use `next` pointers to connect the list around the player node
- Then, we'll free the node itself that we don't need anymore
Removing a player node

If we want to remove the Second Player

A program's memory (not to scale)
Skipping the player node

Alter the First Player's next to bypass the player node we're removing.
Freeing the removed node

Free the memory from the now bypassed player node

A program's memory (not to scale)

First Player

Second Player

Third Player

Free this node

First Player: MARC

Second Player: AANG

Third Player: NULL

head

Next

Next

Next

NULL
Finding the right player

Loop until you find the right match

This is very similar to finding the insertion point earlier
Removing a player

Having found the player node, remove it from the list

```c
if (curr != NULL) {
    // if we didn't reach the end of the list,
    // we found the right player
    if (prev == NULL) {
        // it's the first player
        head = curr->next;
    } else {
        prev->next = curr->next;
    }
    free(curr);
}
return head;
```
Break Time

Keeping track of your own code projects

- Using **git** is a really handy way to keep backups of your work
- GitHub and BitBucket are two providers that will give you free online repositories to store your code
- Graphical Interfaces are available for git (GitHub Desktop and Sourcetree respectively)
- It takes some time to get familiar with how these work . . . but you can start practicing now!
The Battle Royale

In a Battle Royale, people are removed from the game one at a time until only one person is left. They are the winner!

- We can create a list of players
- We can make sure it's in a nice alphabetical order
- We can remove a single player from the list
- Now we need to remove players one at a time
- When there's only one left, they are the winner!
Once our list is created, we can loop through the game

- We print out the player list
- (we might want to modify the print function to tell us how many players are left in the game!)
- Our user will tell us who was knocked out
- If there's only one player left, we stop looping
The Game Loop

This will keep running until we find a winner

```c
// A game loop that runs until only one player is left
while (print_players(head) > 1) {
    printf("Who just got knocked out?\n");
    char ko_name[MAX_NAME_LENGTH];
    fgets(ko_name, MAX_NAME_LENGTH, stdin);
    if (ko_name[strlen(ko_name) - 1] == '\n') {
        ko_name[strlen(ko_name) - 1] = '\0'
    }
    head = remove_player(ko_name, head);
    printf("--------\n");
}
printf("The winner is: %s\n", head->name);
```
Cleaning Up

Remember, All memory allocated (by malloc) needs to be freed

- We can run `dcc --leakcheck` to see whether there's leaking memory
- What do we find?
- There are pieces of memory we've allocated that we're not freeing!

Let's write a function that frees a whole linked list

- Loop through the list, freeing the nodes
- Just be careful not to free one that we still need the pointer from!
Looping to free nodes

A program's memory (not to scale)

First Node
- Next: 3

Second Node
- Next: 2

Third Node
- Next: 1

NULL

head

Loop pointer
Looping to free nodes

A program's memory (not to scale)

First Node
- Next: 3
- Pointer to node we're freeing

Second Node
- Next: 2
- Loop pointer

Third Node
- Next: 1
- Loop pointer is copied from First Node's next before we free First Node

Save a pointer to the node we're freeing

Head

Pointer to node we're freeing
Looping to free nodes

A program's memory (not to scale)

We can free the node now that we've copied its Next

Pointer to node we're freeing

Loop pointer

head

First Node

Next

3

Second Node

Next

2

Third Node

Next

1

NULL
Looping to free nodes

A program's memory (not to scale)

First Node
- Next 3

Second Node
- Next 2

Third Node
- Next 1

Pointer to node we're freeing

Loop pointer

Move our pointers along to the next nodes
Code to free a linked list

// Loop through a list and free all the allocated memory
void free_list(struct node *n) {
  while(n != NULL) {
    // keep track of the current node
    struct node *rem_node = n;

    // move the looping pointer to the next node
    n = n->next;

    // free the current node
    free(rem_node);
  }
}
Battle Royale, the Linked Lists demo

What have we written in this program?

- Creation of nodes
- Looping through a list
- Insertion of nodes into specific locations
- Finding locations using loops
- Removal of nodes
- Managing memory (allocation and freeing)
A Challenge - randomisation

Can we remove a random player from the list?

- Look up the functions `rand()` and `srand()` in the C Standard Library
- We can generate a random number and loop that many times into the list
- Then remove that player
- We will probably want to track how many items are in the list also . . .
What did we cover today?

Linked Lists

- Removal from a list
- Finding and removing a specific node
- Memory cleaning
