COMP9444 17s2 Autoencoders 2 COMP9444 17s2 Autoencoders

Recall: Encoder Networks

Inputs	Outputs
10000	10000
01000	01000
00100	00100
00010	00010
00001	00001

- identity mapping through a bottleneck
- also called N-M-N task
- used to investigate hidden unit representations

COMP9444 17s2 Autoencoders

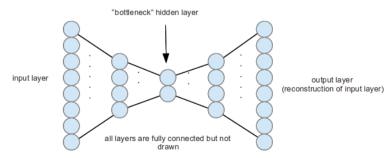

Outline

- Autoencoder Networks (14.1)
- Regularized Autoencoders (14.2)
- Stochastic Encoders and Decoders (14.4)
- Generative Models
- Variational Autoencoders (20.10.3)

COMP9444 © Alan Blair, 2017

Autoencoder Networks

COMP9444

- output is trained to reproduce the input as closely as possible
- activations normally pass through a bottleneck, so the network is forced to compress the data in some way
- like the RBM, Autoencoders can be used to automatically extract abstract features from the input

Autoencoder Networks

If the encoder computes z = f(x) and the decoder computes g(f(x)) then we aim to minimize some distance function between x and g(f(x))

$$E = L(x, g(f(x)))$$

Greedy Layerwise Pretraining

- Autoencoders can be used as an alternative to Restricted Bolzmann Machines, for greedy layerwise pretraining.
- An autoencoder with one hidden layer is trained to reconstruct the inputs. The first layer (encoder) of this network becomes the first layer of the deep network.
- Each subsequent layer is then trained to reconstruct the previous layer.
- A final classification layer is then added to the resulting deep network, and the whole thing is trained by backpropagation.

Autoencoder as Pretraining

- after an autoencoder is trained, the decoder part can be removed and replaced with, for example, a classification layer
- this new network can then be trained by backpropagaiton
- the features learned by the autoencoder then serve as initial weights for the supervised learning task

COMP9444 © Alan Blair, 2017

Avoiding Trivial Identity

- if there are more hidden nodes than inputs (which often happens in image processing) there is a risk the network may learn a trivial identity mapping from input to output
- we generally to avoid this by introducing some form of regularization

7

COMP9444 17s2 Autoencoders 8 COMP9444 17s2 Autoencoders 9

Regularized Autoencoders (14.2)

- sparse autoencoders
- autoencoders with dropout at hidden layer(s)
- contractive autoencoders
- denoising autoencoders

COMP9444 17s2 Autoencoders 10

Contractive Autoencoder (14.2.3)

 \blacksquare another popular penalty term is the L₂-norm of the derivatives of the hidden units with respect to the inputs

$$E = L(x, g(f(x)) + \lambda \sum_{i} ||\nabla_{x} h_{i}||^{2}$$

this forces the model to learn hidden features that do not change much when the training inputs x are slightly altered

Sparse Autoencoder (14.2.1)

- one way to regularize an autoencoder is to add a penalty term to the cost function, based on the hidden unit activations
- this is analogous to the weight decay term we previously used for supervised learning
- one popular choice is to penalize the sum of the absolute values of the activations in the hidden layer

$$E = L(x, g(f(x)) + \lambda \sum_{i} |h_{i}|$$

■ this is sometimes known as L₁-regularization (because it involves the absolute value rather than the square); it can encourage some of the hidden units to go to zero, thus producing a sparse representation

COMP9444 17s2 Autoencoders

Denoising Autoencoder (14.2.2)

Another regularization method, similar to contractive autoencoder, is to add noise to the inputs, but train the network to recover the original input

```
repeat: sample a training item x^{(i)} generate a corrupted version \tilde{x} of x^{(i)} train to reduce E = L\left(x^{(i)}, g(f(\tilde{x}))\right) end
```

COMP9444

Cost Functions and Probability

- We saw previously how the loss (cost) function at the output of a feedforward neural network (with parameters θ) can be seen as defining a probability distribution $p_{\theta}(x)$ over the outputs. We then train to maximize the log of the probability of the target values.
 - squared error assumes an underlying Gaussian distribution, whose mean is the output of the network
 - cross entropy assumes a Bernoulli distribution, with probability equal to the output of the network
 - softmax assumes a Boltzmann distribution

Generative Models

- Sometimes, as well as reproducing the training items $\{x^{(i)}\}$, we also want to be able to use the decoder to generate new items which are of a similar "style" to the training items.
- In other words, we want to be able to choose latent variables z from a standard Normal distribution p(z), feed these values of z to the decoder, and have it produce a new item x which is somehow similar to the training items.
- Generative models can be:
 - explicit (Variational Autoencoders)
 - ▶ implicit (Generative Adversarial Networks)

Stochastic Encoders and Decoders (14.4)

- For autoencoders, the decoder can be seen as defining a conditional probability distribution $p_{\theta}(x|z)$ of output x for a certain value z of the hidden or "latent" variables.
- In some cases, the encoder can also be seen as defining a conditional probability distribution $q_{\phi}(z|x)$ of latent variables z based on an input x.
- We have seen an example of this with the Restricted Boltzmann Machine, where $q_{\phi}(z|x)$ and $p_{\theta}(x|z)$ were Bernoulli distributions.

COMP9444 © Alan Blair, 2017

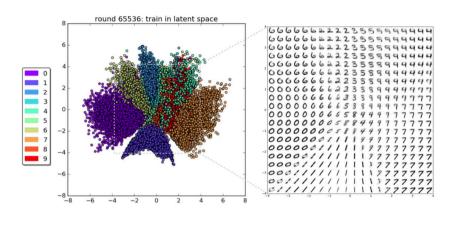

Variational Autoencoder (20.10.3)

Instead of producing a single z for each $x^{(i)}$, the encoder (with parameters ϕ) can be made to produce a mean $\mu_{z|x^{(i)}}$ and standard deviation $\Sigma_{z|x^{(i)}}$. This defines a conditional (Normal) probability distribution $q_{\phi}(z|x^{(i)})$. We then train the system to maximize

$$\mathbf{E}_{z \sim q_{\phi}(z|x^{(i)})}[\log p_{\theta}(x^{(i)}|z)] - D_{\text{KL}}(q_{\phi}(z|x^{(i)})||p(z))$$

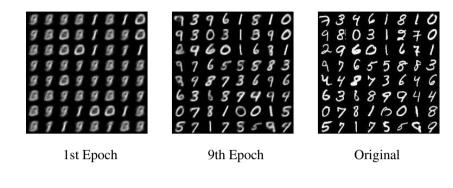

- the first term enforces that any sample z drawn from the conditional distribution $q_{\phi}(z|x^{(i)})$ should, when fed to the decoder, produce somthing approximating $x^{(i)}$
- the second term encourages $q_{\phi}(z|x^{(i)})$ to approximate p(z)
- in practice, the distributions $q_{\phi}(z|x^{(i)})$ for various $x^{(i)}$ will occupy complementary regions within the overall distribution p(z)

Autoencoders

COMP9444 17s2 Autoencoders

Variational Autoencoder Faces

Variational Autoencoder

- Variational Autoencoder produces reasonable results
- tends to produce blurry images
- often end up using only a small number of the dimensions available to z
