Convolutional Networks

COMP9444

Suppose we want to classify an image as a bird, sunset, dog, cat, etc.

If we can identify features such as feather, eye, or beak which provide useful information in one part of the image, then those features are likely to also be relevant in another part of the image.

We can exploit this regularity by using a convolution layer which applies the same weights to different parts of the image. COMP9444 20T3 Convolutional Networks

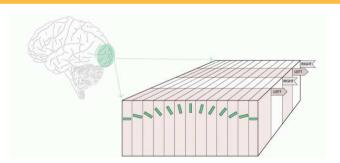

Outline

- Convolutional Networks (7.9)
- Softmax (6.2.2)
- Convolution Operator (9.1-9.2)
- Max Pooling (9.3-9.4)
- Stride (9.5)

Hubel and Weisel - Visual Cortex

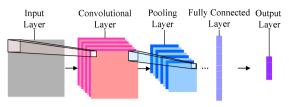

- cells in the visual cortex respond to lines at different angles
- cells in V2 respond to more sophisticated visual features
- Convolutional Neural Networks are inspired by this neuroanatomy
- CNN's can now be simulated with massive parallelism, using GPU's

COMP9444 20T3 Convolutional Networks 4 COMP9444 20T3 Convolutional Networks

Convolutional Network Components

- **convolution layers**: extract shift-invariant features from the previous layer
- **subsampling or pooling layers**: combine the activations of multiple units from the previous layer into one unit
- fully connected layers: collect spatially diffuse information
- **output layer**: choose between classes

CIFAR Image Examples

MNIST Handwritten Digit Examples

Convolutional Network Architecture

There can be multiple steps of convolution followed by pooling, before reaching the fully connected layers.

Note how pooling reduces the size of the feature map (usually, by half in each direction).

COMP9444 20T3 Convolutional Networks 8 COMP9444 20T3 Convolutional Networks

Softmax (6.2.2)

Consider a classification task with N classes, and assume z_j is the output of the unit corresponding to class j.

We assume the network's estimate of the probability of each class j is proportional to $\exp(z_j)$. Because the probabilites must add up to 1, we need to normalize by dividing by their sum:

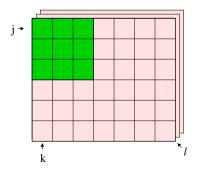

$$Prob(i) = \frac{\exp(z_i)}{\sum_{j=1}^{N} \exp(z_j)}$$
$$log Prob(i) = z_i - log \sum_{j=1}^{N} \exp(z_j)$$

If the correct class is i, we can treat $-\log \operatorname{Prob}(i)$ as our cost function. The first term pushes up the correct class i, while the second term mainly pushes down the incorrect class j with the highest activation (if $j \neq i$).

COMP9444 20T3 Convolutional Networks 10 COMP9444 20T3

Convolutional Neural Networks

Assume the original image is $J \times K$, with L channels.

We apply an $M \times N$ "filter" to these inputs to compute one hidden unit in the convolution layer. In this example J = 6, K = 7, L = 3, M = 3, N = 3.

Convolution Operator

Continuous convolution

$$s(t) = (x*w)(t) = \int x(a)w(t-a)da$$

Discrete convolution

COMP9444

$$s(t) = (x * w)(t) = \sum_{a = -\infty}^{\infty} x(a)w(t - a)$$

Two-dimensional convolution

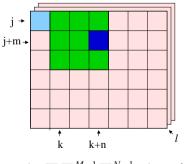

$$S(j,k) = (K*I)(j,k) = \sum_{m} \sum_{n} K(m,n)I(j+m,k+n)$$

Note: Theoreticians sometimes write I(j-m,k-n) so that the operator is commutative. But, computationally, it is easier to write it with a plus sign.

COMP9444 (c) Alan Blair. 2017-20

COMP9444 20T3 Convolutional Networks

Convolutional Neural Networks

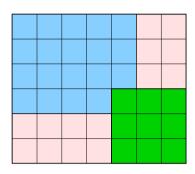

$$Z_{j,k}^{i} = g\left(b^{i} + \sum_{l} \sum_{m=0}^{M-1} \sum_{n=0}^{N-1} K_{l,m,n}^{i} V_{j+m,k+n}^{l}\right)$$

The same weights are applied to the next $M \times N$ block of inputs, to compute the next hidden unit in the convolution layer ("weight sharing").

11

15

Convolutional Neural Networks

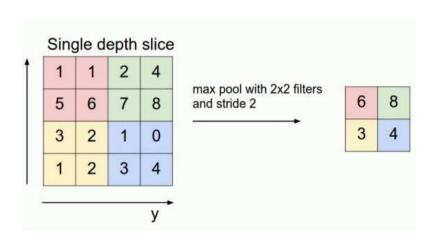

Convolutional Networks

If the original image size is $J \times K$ and the filter is size $M \times N$, the convolution layer will be $(J+1-M) \times (K+1-N)$

COMP9444 © Alan Blair, 2017-20

COMP9444 20T3 Convolutional Networks 14

Max Pooling (9.3-9.4)

Example: LeNet

For example, in the first convolutional layer of LeNet,

$$J = K = 32, M = N = 5.$$

The width of the next layer is

$$J+1-M=32+1-5=28$$

Question: If there are 6 filters in this layer, compute the number of:

weights per neuron?

neurons?

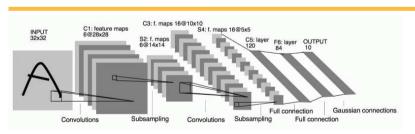

connections?

independent parameters?

COMP9444 © Alan Blair, 2017-20

COMP9444 20T3 Convolutional Networks

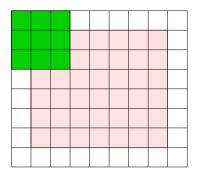

Example: LeNet trained on MNIST

The 5×5 window of the first convolution layer extracts from the original 32×32 image a 28×28 array of features. Subsampling then halves this size to 14×14 . The second Convolution layer uses another 5×5 window to extract a 10×10 array of features, which the second subsampling layer reduces to 5×5 . These activations then pass through two fully connected layers into the 10 output units corresponding to the digits '0' to '9'.

COMP9444 20T3 Convolutional Networks 16 COMP9444 20T3 Convolutional Networks

Convolution with Zero Padding

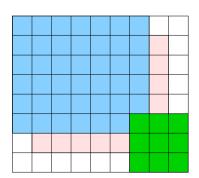

Sometimes, we treat the off-edge inputs as zero (or some other value).

COMP9444 (C) Alan Blair, 2017-20

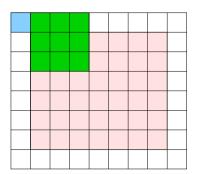

COMP9444 20T3 Convolutional Networks 18 COMP9444 20T3 Convolutional Networks 19

Convolution with Zero Padding

With Zero Padding, the convolution layer is the same size as the original image (or the previous layer).

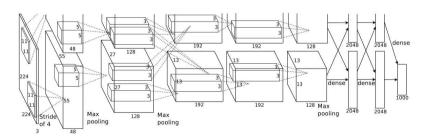

Convolution with Zero Padding

This is known as "Zero-Padding".

COMP9444 © Alan Blair, 2017-20

Example: AlexNet (2012)

- 5 convolutional layers + 3 fully connected layers
- max pooling with overlapping stride
- softmax with 1000 classes

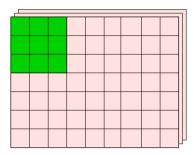

COMP9444

■ 2 parallel GPUs which interact only at certain layers

COMP9444 © Alan Blair, 2017-20

© Alan Blair, 2017-20

Stride (9.5)

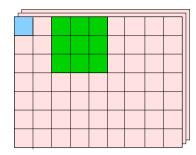

Assume the original image is $J \times K$, with L channels.

We again apply an $M \times N$ filter, but this time with a "stride" of s > 1.

In this example J = 7, K = 9, L = 3, M = 3, N = 3, s = 2.

COMP9444 © Alan Blair, 2017-20

Stride

$$Z_{j,k}^{i} = g(b^{i} + \sum_{l} \sum_{m=0}^{M-1} \sum_{n=0}^{N-1} K_{l,m,n}^{i} V_{j+m,k+n}^{l})$$

The same formula is used, but j and k are now incremented by s each time. The number of free parameters is $1 + L \times M \times N$

COMP9444 20T3

Convolutional Networks

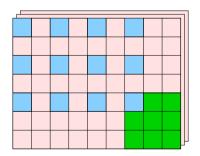

COMP9444 20T3

22

Convolutional Networks

23

Stride Dimensions

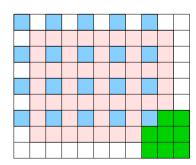

j takes on the values $0, s, 2s, \dots, (J-M)$

k takes on the values $0, s, 2s, \dots, (K - N)$

The next layer is (1 + (J - M)/s) by (1 + (K - N)/s)

Stride with Zero Padding

When combined with zero padding of width P,

j takes on the values $0, s, 2s, \dots, (J+2P-M)$

k takes on the values $0, s, 2s, \dots, (K+2P-N)$

The next layer is (1 + (J+2P-M)/s) by (1 + (K+2P-N)/s)

COMP9444 20T3 Convolutional Networks 24 COMP9444 20T3 Convolutional Networks

Example: AlexNet Conv Layer 1

For example, in the first convolutional layer of AlexNet,

$$J = K = 224, P = 2, M = N = 11, s = 4.$$

The width of the next layer is

$$1 + (J + 2P - M)/s = 1 + (224 + 2 \times 2 - 11)/4 = 55$$

Question: If there are 96 filters in this layer, compute the number of:

weights per neuron?

neurons?

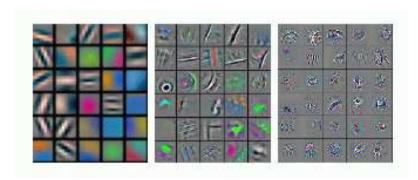

connections?

independent parameters?

Overlapping Pooling

If the previous layer is $J \times K$, and max pooling is applied with width F and stride s, the size of the next layer will be

$$(1+(J-F)/s) \times (1+(K-F)/s)$$

Question: If max pooling with width 3 and stride 2 is applied to the features of size 55×55 in the first convolutional layer of AlexNet, what is the size of the next layer?

Answer:

Question: How many independent parameters does this add to the model?

Answer:
